Abstract: The presence of glycoside derivatives of $1\alpha,25(\text{OH})_2\text{D}_3$ endows plants to gradual release of the free bioactive form of $1\alpha,25(\text{OH})_2\text{D}_3$ from its glycoconjugates by endogenous animal tissue glycosidases. This results in increased half-life of the hormone in blood when purified plant fractions are administered for therapeutic purposes. In this work, we evaluated the role $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides enriched natural product (Solbone A) from Solanum glaucophyllum leaf extract compared with synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ on myogenic differentiation in C2C12 myoblasts. For these, differentiation markers and myogenic parameters were studied in C2C12 myoblasts. Results showed that Solbone A, likewise the synthetic hormone, increased creatine kinase activity at day 2 after differentiation induction (60%, $p < 0.05$). Solbone A and synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ increased vitamin D3 receptor protein expression at 10 nM (50 and 30 %, respectively) and the transcription factor myogenin (80%, $p < 0.05$). However, tropomyosin expression by both compounds was induced at 1 nM (20%, $p < 0.05$). In addition, myosin heavy chain (MHC) protein expression was increased 50 % at day 4 of differentiation. Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ had no effects on myogenin nor MHC cell localization. Cellular mass increased with myogenesis progression, being Solbone A more effective than synthetic $1\alpha,25(\text{OH})_2\text{D}_3$. Finally, Solbone A, as well as synthetic $1\alpha,25(\text{OH})_2\text{D}_3$, augmented the index fusion of cultured muscle fibers. In conclusion, these results demonstrated that Solbone A exhibit at least equal or greater effects on early myoblast differentiation as synthetic hormone, suggesting that plant glycosides could be an effective, accessible and cheaper substitute for synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ to promote muscle growth

Highlights

- Solbone and $1\alpha,25(\text{OH})_2\text{D}_3$ enhanced CK activity at the onset of C2C12 cell myogenesis
- Solbone, similar to synthetic $1\alpha,25(\text{OH})_2\text{D}_3$, induced VDR and myogenin expression.
- Solbone and synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ increased tropomyosin and MHC expression.
- Solbone stimulated myotube formation at the onset of C2C12 cell myogenesis

Abstract

1
2
3 The presence of glycoside derivatives of $1\alpha,25(\text{OH})_2\text{D}_3$ endows plants to
4 gradual release of the free bioactive form of $1\alpha,25(\text{OH})_2\text{D}_3$ from its
5 glycoconjugates by endogenous animal tissue glycosidases. This results in
6 increased half-life of the hormone in blood when purified plant fractions are
7 administered for therapeutic purposes. In this work, we evaluated the role
8 $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides enriched natural product (Solbone A) from *Solanum*
9 *glaucophyllum* leaf extract compared with synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ on myogenic
10 differentiation in C2C12 myoblasts. For these, differentiation markers and
11 myogenic parameters were studied in C2C12 myoblasts. Results showed that
12 Solbone A, likewise the synthetic hormone, increased creatine kinase activity at
13 day 2 after differentiation induction (60%, $p < 0.05$). Solbone A and synthetic
14 $1\alpha,25(\text{OH})_2\text{D}_3$ increased vitamin D_3 receptor protein expression at 10 nM (50
15 and 30 %, respectively) and the transcription factor myogenin (80%, $p < 0.05$).
16 However, tropomyosin expression by both compounds was induced at 1 nM
17 (20%, $p < 0.05$). In addition, myosin heavy chain (MHC) protein expression was
18 increased 50 % at day 4 of differentiation. Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$
19 had no effects on myogenin nor MHC cell localization. Cellular mass increased
20 with myogenesis progression, being Solbone A more effective than synthetic
21 $1\alpha,25(\text{OH})_2\text{D}_3$. Finally, Solbone A, as well as synthetic $1\alpha,25(\text{OH})_2\text{D}_3$,
22 augmented the index fusion of cultured muscle fibers. In conclusion, these
23 results demonstrated that Solbone A exhibit at least equal or greater effects on
24 early myoblast differentiation as synthetic hormone, suggesting that plant
25 glycosides could be an effective, accessible and cheaper substitute for synthetic
26 $1\alpha,25(\text{OH})_2\text{D}_3$ to promote muscle growth.

Introduction

1
2 Intensive poultry industry for producing both, broilers and laying hens, as a
3
4 source of food is a steadily increasing animal husbandry activity. Nevertheless,
5
6 due to the need of faster development rates, industry performs maneuvers that
7
8 may cause the appearance of various health problems with the consequent
9
10 economic loss. A balanced diet turns out to be essential for good health and
11
12 vigor of domesticated birds. Among dietary supplements, the bioactive derivate
13
14 of vitamin D₃, 1 α ,25-dihydroxyvitamin D₃ (1 α ,25(OH)₂D₃), improves both health
15
16 and muscle strength of broilers correcting frequent myopathies. Supporting the
17
18 action on muscle physiology, work derived from our laboratory demonstrated
19
20 the presence of the vitamin D receptor (VDR) in monolayers of chick myoblasts
21
22 [1] and myotubes (multinucleated cells) as well as in chicken skeletal muscle
23
24 matured in vivo [2]. Unfortunately elevated production costs of synthetic
25
26 1 α ,25(OH)₂D₃ makes unfeasible to use it as supplement for poultry diets. Of
27
28 relevance, various flowering plants have been shown to contain 1 α ,25(OH)₂D₃
29
30 and related vitamin D₃ metabolites as detected by highly specific and sensitive
31
32 biological and chemical procedures [3]. Among the plants in which vitamin D₃
33
34 metabolites have been found, *Solanum glaucophyllum* is the one which
35
36 accumulates 1 α ,25(OH)₂D₃ to the greatest extent.
37
38
39 In addition, 1 α ,25(OH)₂D₃ and other vitamin D₃ related sterols are present as
40
41 glycoconjugates as well as in free forms in variable proportions [4]. The
42
43 presence of glycoside derivatives of 1 α ,25(OH)₂D₃ is a conspicuous feature
44
45 which endows plants with special pharmacokinetic properties, due to gradual
46
47 release of the free bioactive form of 1 α ,25(OH)₂D₃ from its glycoconjugates by
48
49 endogenous animal tissue glycosidases. This results in increased half-life of the
50
51 hormone in blood when purified plant fractions are administered for therapeutic
52

1 purposes [5;6]. Taken altogether, the plant kingdom represents a cheaper and
2 non-polluting source of natural products of commercial interest to cover the
3 widespread nutritional and veterinary medical application of $1\alpha,25(\text{OH})_2\text{D}_3$.
4 Before exerting its actions, vitamin D_3 must be converted to a metabolically
5 active form by hydroxylation reactions to render $1\alpha,25$ -dihydroxyvitamin D_3
6 ($1\alpha,25(\text{OH})_2\text{D}_3$). This bioactive derivative plays a critical role in mineral
7 homeostasis, regulation of cell growth and differentiation, muscle intracellular
8 Ca^{2+} levels and contractility; vascular, endocrine and reproductive functions and
9 immunomodulation [7;8].

10 It is widely known that vitamin D deficiency, like osteomalacia, or metabolic
11 abnormalities such as hypocalcemia, hypophosphatemia, and
12 hyperparathyroidism, are associated with myopathies characterized by muscle
13 weakness, hypotonia, and atrophy in addition to weak bones. This has been
14 confirmed by electrophysiological studies revealing in vitamin D-deficient chicks
15 muscle weakness due to abnormal kinetics of muscle contraction [9] and
16 histological observations of muscle [10], Also, Rodman et al. [11] showed
17 alterations in skeletal muscle calcium metabolism not secondary to variations in
18 plasma calcium and phosphate and atrophy predominantly of type II fibers,
19 these processes being exacerbated by ageing. Accordingly, there is evidence
20 that the administration of vitamin D bioactive derivatives reverse impaired
21 muscle function and structure as well as improve normal tissue performance.

22 Scarce information is available regarding the mechanism by which
23 $1\alpha,25(\text{OH})_2\text{D}_3$ exerts myogenic differentiation at the cellular and/or molecular
24 level. The objective of this work was to evaluate the role of the natural product
25 Solbone composed of $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides compared with synthetic
26 $1\alpha,25(\text{OH})_2\text{D}_3$ on myogenic differentiation in C2C12 myoblasts.

Experimental

Chemicals

$1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone[®] were kindly provided by Herbonis AG (Basel, Switzerland). Dulbecco's modified Eagle's medium (DMEM) low glucose, with l-glutamine and HEPES, without phenol red, was from US Biological (Swampscott, MA, USA). Fetal bovine serum (FBS) was from Sigma–Aldrich Co. (St. Louis, MO, USA). Sterile horse serum (HS) was from Natocor (Córdoba, Argentina). Primary antibodies anti-myogenin, anti-tropomyosin, anti-myosin heavy chain, anti-tubulin, anti-VDR and secondary antibodies goat anti-rabbit and rabbit anti-mouse horse radish peroxidase-conjugated IgG were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). 4',6-diamidino-2'-phenylindole dihydrochloride (DAPI) and MitoTracker Red (MitoTracker Red CMXRos) dyes and Alexa Fluor 488-conjugated anti-mouse secondary antibody were purchased from Molecular Probes (Eugene, OR, USA). The Western Lighting Plus enhanced chemiluminescence substrate (ECL) was from PerkinElmer, Inc. (Boston, USA). The creatine kinase (CK) assay kit monotest CK NAC was from Wiener Lab. (Rosario, Argentina). The C2C12 murine skeletal muscle cell line was from American Type Culture Collection (Manassas, VA). All other reagents were of analytical grade.

Vegetal material

Solbone A (Herbonis AG) is a water soluble dried leaves extract of the plant *Solanum glaucophyllum* standardized to 50 ppm active vitamin D₃ present as $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosid (1-[β -D-glucopyranosyl]- $1\alpha,25$ -dihydroxycholecalciferol) [12].

Cell Culture and treatment

1 The murine skeletal muscle cell line C2C12 is a good model for studying
2 myogenesis. C2C12 cells were seeded at an appropriate density (120,000
3 cells/cm²) in Petri dishes (100 mm diameter) and cultured with DMEM
4 supplemented with 10% heat-inactivated (30 min, 56°C) fetal bovine serum
5 (FBS), 1% nystatine, and 2% streptomycin, without phenol red (GM, growth
6 medium). Cells were incubated at 37°C under a humidified atmosphere of 5%
7 CO₂ in air. Under these conditions, C2C12 myoblasts resemble the activated
8 satellite cells that surround the mature myofibers and proliferate and
9 differentiate participating in the repair of the tissue when a cellular injury exists
10 [13].

14
15
16
17
18
19
20
21
22
23

24 To promote myoblast differentiation, C2C12 cells in GM grown up to 70-80 % of
25 confluence were replaced by DMEM without phenol red, supplemented with 1%
26 horse serum (HS, DM, differentiation medium) and cultured up to four days. DM
27 was changed every day.
28
29
30
31
32
33

34 To study the effects of Solbone A, active vitamin D₃ present as 1 α ,25-
35 Dihydroxyvitamin D₃-glycosides, compared to the synthetic 1 α ,25(OH)₂D₃, cells
36 were incubated with water dissolved Solbone A and diluted to 1 or 10 nM
37 (calculated as total 1 α ,25(OH)₂D₃) in DMEM + HS from the beginning of the
38 differentiation induction and during the experimental period. Another groups of
39 cells were incubated with 1 or 10 nM of synthetic hormone 1 α ,25(OH)₂D₃
40 dissolved in less than 0.01% ethanol as vehicle. Simultaneously, control cells
41 were incubated with the respective vehicles, water or ethanol. The
42 concentrations of 1 α ,25(OH)₂D₃ employed in the experimental design were
43 based on prior dose-response studies performed in our laboratory [14].

54
55
56
57
58

59 Because of the short half-life of 1 α ,25(OH)₂D₃, the cell culture media were
60 replaced daily.
61
62
63
64
65

Phase-contrast and Fluorescence Microscopy

1
2 Cells were analyzed with phase-contrast microscope Olympus CK2-TR with
3
4 photographic system using 10X, 20X and 40X objectives.
5

6
7 For fluorescence studies, cells were stained with MitoTracker Red prepared in
8
9 DMSO and then added to culture medium at a final concentration of 1 mmol/l.
10
11 After 15-30 min incubation at 37°C, the cells were washed with PBS (pH 7.4, 8
12
13 g/l NaCl, 0.2 g/l KCl, 0.24 g/l KH₂PO₄, and 1.44 g/l Na₂HPO₄) and fixed with
14
15 methanol at - 20 °C for 30 min. For DAPI staining, fixed cells were incubated for
16
17 30 min at room temperature in darkness with 1:500 of a stock solution of DAPI
18
19 (5 mg/ml) and washed with PBS. For immunocytochemistry, cells were fixed as
20
21 before. After fixation, cells were rinsed three times with PBS, and nonspecific
22
23 sites were blocked for 1 h in 2 % BSA. Then, cells were incubated with
24
25 appropriate primary antibodies dilution overnight at 4 °C. The primary antibodies
26
27 were recognized by fluorophore-conjugated secondary antibodies. In all cases,
28
29 cells were examined using a fluorescence microscope (NIKON Eclipse Ti-S)
30
31 equipped with standard filter sets to capture fluorescent signals, and images
32
33 were collected using a digital camera.
34

40

Cell lysates protein content determination and cellular mass calculation

41
42 Cells were lysed using a buffer containing 50 mM Tris-HCl pH 7.4, 150 mM
43
44 NaCl, 0.2 mM Na₂VO₄, 2 mM EDTA, 25 mM NaF, 1 mM PMSF, 1% NP40,
45
46 leupeptin 20 µg/ml and aprotinin 20 µg/ml. Whole cell lysates were collected by
47
48 aspiration, weighed on an analytical balance and centrifuged at 12,000 g during
49
50 15 min. The protein content of the supernatant was quantified by the Bradford
51
52 procedure. Cellular mass was calculated multiplying the protein content by the
53
54 weight of the sample and data are expressed as percent variation with respect
55
56 to the day 0 of differentiation.
57
58
59
60
61
62
63
64
65

Creatine kinase assay

1
2 Creatine kinase (CK) activity was measured in whole cell lysates by coupling
3
4 the hexokinase and glucose-6-phosphate dehydrogenase reactions according
5
6 to manufacturer instructions (kit monotest CK NAC from Wiener lab., Argentina).
7
8
9 One unit of activity represents 1 μmol of NADPH generated per min per mg
10
11 protein.
12

Western Blot analysis

13
14 Equal amounts of protein (15-20 μg) from each sample were dissolved in
15
16 Laemmli sample buffer [15] and separated on 10 % sodium dodecyl sulfate–
17
18 polyacrylamide gel electrophoresis (SDS-PAGE). Proteins were transferred to a
19
20 polyvinylidene difluoride (PVDF) membrane. Unspecific sites on the membrane
21
22 were blocked with TBST buffer (50 mM Tris-HCl, pH 7.4, 200 mM NaCl, 0.1%
23
24 Tween-20) containing 5% dry milk for 1 h at room temperature and then, they
25
26 were subject to immunoblotting using different primary antibodies [anti-
27
28 myogenin (1:1000), anti-tropomyosin (1:1000), anti- myosin heavy chain (1:500)
29
30 and anti-tubulin (1:5000), Anti-VDR (1:4000)] overnight at 4°C. Membranes
31
32 were then washed three times in TBST, incubated in TBST containing 1% dry
33
34 milk with peroxidase-conjugated secondary antibody for 1 h at room
35
36 temperature and washed again three times with TBST. Next, membranes were
37
38 visualized using an enhanced chemiluminescence technique (ECL) according to
39
40 the manufacturer's instructions. Blots were quantified using image J software, a
41
42 public domain program, developed at the National Institutes of Health. To strip
43
44 the membranes for reprobing with other antibodies, the membranes were
45
46 washed 10 min in TBST, incubated in stripping buffer (62.5 mM Tris-HCl, pH
47
48 6.8, 2% SDS and 50 mM mercaptoethanol) for 30 min at 55°C, washed 10 min
49
50 in TBST and then blocked and blotted as described above.

Index fusion determination

1
2 Culture cells were stained with MitoTracker Red and DAPI as described in
3
4 “Fluorescence Microscopy”. Images with both dyes were collected using a
5
6 digital camera and were merged. Nuclei were counted in ten randomly chosen
7
8 microscope fields (2 culture dishes, 5 fields in each dish) at an objective
9
10 magnification of 40 X. One microscope field usually contained between 150 and
11
12 250 nuclei. The fusion index is defined as the number of nuclei in myotubes
13
14 divided by the total number of nuclei.
15
16
17

Statistical Analysis

18
19 All experiments were performed at least three times. Quantitative results were
20
21 expressed as means \pm SD. Statistical analysis was carried out using InfoStat
22
23 software. Analysis of variance (ANOVA) was used to determine differences
24
25 among mean values between control and treated conditions, which were then,
26
27 compared using the *post hoc* tests of multiple comparisons Bonferroni or
28
29 Fisher’s Least Significant Difference (LSD). Differences were considered
30
31 significant at $p < 0.05$.

40

Results

41
42 To investigate the effects of $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides enriched natural product
43
44 Solbone A on the differentiation of muscle cells, the murine skeletal muscle cell
45
46 line C2C12 in differentiation state was chosen as experimental model. In
47
48 previous studies, we have characterized a differentiation pattern typical of the
49
50 onset of myogenesis (data not shown). In the proliferative state, non confluent
51
52 myoblasts were polygonal and had only one nucleus in growth medium (GM).
53
54 After switching culture conditions from GM to differentiation medium (DM),
55
56 myoblasts differentiation was revealed showing typically morphological changes
57
58
59
60
61
62
63
64
65

1 such as alignment, elongation and fusion of mononucleated cells to
2 multinucleated myotubes whereas a subpopulation of cells remained
3 undifferentiated as reserve cells. In parallel to these morphological changes, the
4 total protein content and specific biochemical markers of muscle differentiation
5 such as creatine kinase, myogenin, tropomyosin and myosin were raised during
6 the first seven days of the progression of differentiation as reported before (data
7 not shown) [13;16;17]. Under these conditions, the role of the natural product
8 Solbone A on myogenesis was studied and compared to synthetic
9 $1\alpha,25(\text{OH})_2\text{D}_3$.
10

11 First, the activity of the muscle differentiation marker enzyme, creatine kinase
12 (CK), was evaluated in C2C12 myoblasts. Cells were cultured in DM in the
13 presence or absence of 1 nM or 10 nM of Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$
14 or in their absence from 1 to 4 days. CK activity was measured in whole cell
15 lysates as described in Experimental. As expected, CK activity increased
16 according with myogenesis progression. The first day after differentiation
17 induction, 1 nM of synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ increased CK activity whereas
18 Solbone A reached the highest levels at the second day showing an increase of
19 60% above control ($p < 0.05$) (Fig. 1 A). Although similar changes in CK activity
20 were observed in both conditions at 10 nM, the effects of synthetic
21 $1\alpha,25(\text{OH})_2\text{D}_3$ -were more attenuated (30 %; $p < 0.05$) (Fig. 1 B). In view of these
22 results, we evaluated the effects of Solbone A on distinct parameters paying
23 particular attention at the second day of differentiation. Next, to further explore
24 the effects of Solbone A on miogenesis, vitamin D₃ receptor (VDR) expression
25 as well as the myogenic transcription factor myogenin and the early and late
26 muscle specific proteins, tropomyosin and myosin heavy chain (MHC) were
27 evaluated by Western blot analysis. C2C12 cells were cultured in DM and

1 treated with Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ at 1 or 10 nM or in their
2 absence for 2 days. The results shown in Fig. 2 revealed that both compounds
3 statistically increased VDR expression by 30 % and 50 %, respectively
4 ($p < 0.05$). In accordance, cells exposed to 10 nM of Solbone A or synthetic
5 hormone showed a marked rise of the key myogenic regulatory factor myogenin
6 in comparison with control cells (100 % and 70 % respectively, $p < 0.05$) (Fig. 3).
7 However, Solbone A likewise the synthetic hormone statistically increased by
8 20% ($p < 0.05$) the early myogenesis protein marker expression tropomyosin at 1
9 nM at day 2 of differentiation (Fig. 4). Myosin heavy chain (MHC) is a mature
10 muscle cell marker. Thus, the effect of Solbone A on the expression of MHC
11 was measured at days 2 and 4 after differentiation induction. The results shown
12 in Fig 5 revealed that cells exposed to Solbone A 1nM (Fig. 5 A) and 10 nM (Fig
13 5 B) increased MHC expression (30 % and 60 %, respectively; $p < 0.05$) in
14 comparison with control cells at day 2 of myoblast differentiation. Enhanced
15 MHC expression induced by 1 nM of synthetic or natural hormone persisted at
16 day 4 of differentiation (Fig. 5 A) although no statistically significant differences
17 were found at 10 nM of Solbone A (Fig 5 B). Considering the above results, we
18 examined the cellular localization of myogenin and MHC treated with
19 $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides from Solbone A and synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ and
20 compared the effects of both compounds on myotubes formation. After the
21 experimental period cells were fixed, unspecific sites were blocked, and were
22 incubated with appropriate primary antibodies that were then recognized by
23 fluorophore-conjugated secondary antibodies as was described in
24 Experimental. In control condition, myogenin localized mainly to the nucleus
25 while MHC was located in the cytoplasm (Fig. 6). Nevertheless, natural

$1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides from Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ (1 nM or 10 nM) had no effects on the subcellular localization of myogenin nor MHC. Next, we evaluated if the natural $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides enriched Solbone A induces changes on C2C12 cells morphology under the differentiation state. To that end, C2C12 cells were treated in the presence or absence of 1 nM or 10 nM of Solbone A or synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ and cellular mass and index fusion were calculated as described in Experimental. The results shown in Fig. 7 demonstrated that muscle growth measured by cellular mass increased according with myogenesis progression. Solbone A (1 nM or 10 nM) treated cells showed the greatest increase after 4 days of initiated the differentiation (Fig. 7, A and B). Micrographs of 4 days differentiation cultures support this enhancement in the cellular mass which is reflected in the morphology of cultured muscle fibers (Fig. 7, lower panel). As shown in Fig. 8, muscle growth measured by index fusion in 4 days differentiation cultures increased with 1 nM or 10 nM Solbone A treatments as well as with synthetic $1\alpha,25(\text{OH})_2\text{D}_3$. Accordingly, morphological changes in Solbone A treated cells were much more evident than those of synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ reflecting the augment in cell mass. As revealed in the micrographs of 4 days differentiation muscle cell cultures, both concentrations of Solbone A produced a more prominent alignment, elongation and fusion of mononucleated cells to multinucleated myotubes than the control and synthetic $1\alpha,25(\text{OH})_2\text{D}_3$.

Discussion

Intensive poultry industry for producing both, broilers and laying hens, as a source of food is a steadily increasing animal husbandry activity since it can produce meat in a faster and cheaper manner than ruminants in similar

1 systems. Nevertheless, due to the need of faster development rates, industry
2 turns either into genetic manipulation whenever possible in order to obtain races
3 that grow quickly, or more frequently, birds are kept under raising conditions
4 that maximize their growth. However, these maneuvers may cause the
5 appearance of various health problems such as heart failure, injuries, lameness
6 and death. Also, considerable controversy persists regarding the use of human
7 antibiotics to promote growth in animals raised for food. The World Health
8 Organization, the American Medical Association, and the American Public
9 Health Association claim that the use of growth-promoting antibiotics leads to
10 increased antibiotic-resistant infections in humans [18]. Consequently, to
11 minimize these problems, a balanced diet turns out to be essential for good
12 health and vigor of domesticated birds. Among dietary supplements, the use of
13 vitamin D₃ improves both bone health and muscle strength of broilers correcting
14 frequent myopathies [19-21], feedlot steers good health [22] and meat
15 tenderness [23].

16 As we already mentioned, *Solanum glaucophyllum* has been shown to contain
17 the greatest amounts of 1 α ,25(OH)₂D₃ glycoconjugates and related vitamin D₃
18 metabolites among various flowering plants [4]. The natural product Solbone A
19 is a dried leaves extract of this plant [12] and represent the natural source of the
20 active form of vitamin D first available in a cold water soluble form. Among other
21 positive aspects, Solbone A effect starts earlier than regular vitamin D₃ which
22 needs two metabolic steps to become active [24]. The active component of
23 Solbone A is available at the point of entry to the body, where it induces the
24 transport of calcium and phosphorus and therefore is recommended when liver
25 and/or kidney function is impaired, in older animals and in conditions induced by
26 stress [12;25;26].

In order to study the role of the natural product Solbone A compared to synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ on myogenesis, CK activity, VDR and myogenic markers expression, morphological characteristics, cellular mass and index fusion, were evaluated in C2C12 myoblasts. Similarly to synthetic hormone, 1 and 10 nM of Solbone A enhanced CK activity (60% and 30 %, respectively) at day 2 of differentiation induction (Fig. 1). Supporting this observation, it have been reported that, the synthetic hormone increased creatine kinase activity in primary cultured chick myoblasts under differentiated conditions indicating stimulation of myogenesis [27].

$1\alpha,25(\text{OH})_2\text{D}_3$, as other steroid hormones, exerts its action binding to a specific receptor: the vitamin D receptor (VDR), localized commonly in the nucleus [28-31]. We have known for more than 30 years that vitamin D exerts effects on muscle cells at a molecular level [32-35]. However, recent reports suggest that VDR is not detectable in muscle and therefore propose the effects of vitamin D on muscle via an indirect route of action [36;37]. This controversy in the field could be due to differences in the expression of VDR in muscle of different species and throughout the various stages of muscle differentiation [7]. In addition, as we have mention before, we previously reported the presence of the VDR in chick myoblasts [1] and myotubes and in chicken skeletal muscle *in vivo* [2]. Thus, the expression of VDR in muscle tissue further supports a direct role of vitamin D in muscle physiology.

Our study showed that treatment with Solbone A of murine C2C12 cells enhanced VDR expression as does the synthetic hormone, after two days differentiation induction (Fig. 2). In accordance, same amounts of Solbone A showed a marked rise in the key myogenic regulatory factors myogenin like synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ (Fig. 3). In line with our results, it has been reported

1 that $1\alpha,25(\text{OH})_2\text{D}_3$ increases VDR expression, induces its translocation to the
2 nuclei [38] and triggers the synthesis of new proteins involved in muscle cell
3 contractility, proliferation, and differentiation [39]. In addition, $1\alpha,25(\text{OH})_2\text{D}_3$
4 promotes proliferation of C2C12 myoblasts through Akt activation by PI3K and
5 p38 MAPK [35]. Moreover, mice VDR knockout models exhibit smaller muscle
6 fibers, higher levels of Myogenic Regulatory Factors (family of transcription
7 factors that modulate satellite cell differentiation –MRFs-) and persistence of
8 immature muscle gene expression during adult life [34;40]. This phenotype is
9 reversed upon vitamin D administration [34]. Also MyoD, another MRF, was
10 reported to be modulated by $1\alpha,25(\text{OH})_2\text{D}_3$ [38]. Further investigations on the
11 regulatory mechanisms underlying $1\alpha,25(\text{OH})_2\text{D}_3$ -dependent myogenesis are
12 still needed.

13 Solbone A likewise the synthetic hormone increased tropomyosin, the early
14 myogenesis protein marker, expression at day 2 of differentiation (Fig. 4) and
15 raised the expression of the specific mature myotube protein MHC even more
16 than the synthetic hormone (Fig. 5). Of relevance, Src and PI₃K are involved in
17 Akt activation and in MHC and myogenin increased expression by
18 $1\alpha,25(\text{OH})_2\text{D}_3$ [35].

19 Once myogenic cells are committed, they must differentiate and fuse into
20 multinucleated myotubes. Normal physiology of mature muscle fiber requires
21 adequate vitamin D₃ levels, as shown in studies employing animals deprived of
22 vitamin D₃, which were found to generate less than one-half the normal muscle
23 tension in response to repetitive electrical stimulation. In addition, relaxation
24 after muscle contraction is slowed in the vitamin D-deficient chickens [9] These
25 alterations were reversed upon administration of vitamin D₃ and modifying
26 dietary calcium concentration. Also, vitamin D₃ therapy increased calcium

1 content of skeletal muscle mitochondria in vitamin D-deficient chickens. The rise
2 in mitochondrial calcium was correlated with increased force of skeletal muscle
3 contraction [9]. This muscle weakness associated to deficiency of vitamin D₃
4 metabolites results in increased morbidity and mortality of broilers and laying
5 hens observed in large-scale poultry farming, causing thereby considerable
6 economical losses.
7

8
9 Results obtained by cellular mass (Fig. 7) and index fusion (Fig. 8) as well as by
10 image analysis from phase- contrast and fluorescence microscopy revealed that
11 Solbone A improved growth and differentiation of C2C12 cells at the onset of
12 myogenesis.
13

14 While Solbone A represents a natural source enriched in the active form of
15 vitamin D₃, it should not be ignored that, like many other vegetable materials,
16 contains other beneficial compounds such as flavonoids with antioxidant action.
17 The presence of these active principles in the leaves extract could be affecting
18 cell behavior and even exerting a synergistic action with respect to
19 1 α ,25(OH)₂D₃. Moreover, the gradual release of the bioactive form of its free
20 glycoconjugates by endogenous glycosidases presents in animal tissues could
21 result in an increase half-life of the hormone in blood when plants purified
22 fractions are administered for therapeutic purposes representing another
23 beneficial aspect of this natural product.
24

25 Further research is needed to explain whether the isolated 1 α ,25(OH)₂D₃-
26 glycosides or its synergistic action with other compounds are responsible for the
27 effects observed during the onset of C2C12 myoblast differentiation. In
28 conclusion, our data suggest that Solbone A could represent an effective,
29 accessible and economic source of natural 1 α ,25(OH)₂D₃-glycosides to
30 stimulate myoblast growth and differentiation.

3 **Fig. 1. Solbone A as synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ increased creatine kinase**
4 **activity in C2C12 cell myogenesis as a function of culture time.** CK activity
5 of cells exposed to 1 nM (**A**) or 10 nM (**B**) of synthetic ($1\alpha,25(\text{OH})_2\text{D}_3$) or natural
6 $1\alpha,25(\text{OH})_2\text{D}_3$ -glycosides (Solbone A) or in their absence (control) is shown.
7 CK activity represented in bar graphs is expressed as a ratio between treated
8 conditions ($1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone A) versus control referred to day 0 of
9 differentiation. Values are the mean \pm S.D. of three independent experiments.
10 Different letters indicate statistical differences among groups for each day
11 (ANOVA - Bonferroni $p < 0.05$).

26 **Fig. 2. Changes in VDR expression induced by synthetic $1\alpha,25(\text{OH})_2\text{D}_3$**
27 **and Solbone A in C2C12 cell myogenesis at day two of differentiation.**
28 Cells were exposed to 1 nM (**A**) or 10 nM (**B**) of synthetic ($1\alpha,25(\text{OH})_2\text{D}_3$) or
29 natural $1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 2 days.
30 Western blots were performed with anti-VDR and anti-tubulin antibodies. A
31 representative blot from three independent experiments is shown. Protein
32 bands quantification from three independent experiments was done using
33 Image J program. The results (mean \pm S.D.) were then represented in bar
34 graphs as a ratio of VDR protein normalized with tubulin from treated
35 conditions ($1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone A) versus the control. Different letters
36 indicate statistical differences among groups for each concentration (ANOVA -
37 Bonferroni $p < 0.05$).

$1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 2 days. Western blots were performed with anti-myogenin and anti-tubulin antibodies. A representative blot from three independent experiments is shown. Protein bands from three independent experiments were quantified, normalized and expressed as described in legend of Fig. 2. Values represented in bar graphs are the mean \pm S.D. Different letters indicate statistical differences among groups for each concentration (ANOVA - Bonferroni $p < 0.05$).

Fig. 4. Changes in tropomyosin expression induced by synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone A in C2C12 cell myogenesis at day two of differentiation. Cells were exposed to 1 nM (A) or 10 nM (B) of synthetic ($1\alpha,25(\text{OH})_2\text{D}_3$) or natural $1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 2 days. Western blots were performed with anti- tropomyosin and anti-tubulin antibodies. A representative blot from three independent experiments is shown. Protein bands from three independent experiments were quantified, normalized and expressed as described in legend of Fig.2. Values represented in bar graphs are the mean \pm S.D.. Different letters indicate statistical differences among groups for each concentration (ANOVA – LSD Fisher $p < 0.05$).

Fig. 5. Changes in myosin heavy chain (MHC) expression induced by synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone A in C2C12 cell myogenesis as a function of culture time. Cells were exposed to 1 nM (A) or 10 nM (B) of synthetic ($1\alpha,25(\text{OH})_2\text{D}_3$) or natural $1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 2 and 4 days of differentiation. Western blots were performed with anti- tropomyosin and anti-tubulin antibodies. A representative blot from three independent experiments is shown. Protein bands from three

independent experiments were quantified, normalized and expressed as described in legend of Fig.2. Values represented in bar graphs are the mean \pm S.D. Different letters indicate statistical differences among groups for each day (ANOVA – LSD Fisher $p < 0.05$).

Fig. 6. Effects of synthetic $1\alpha,25(\text{OH})_2\text{D}_3$ and Solbone A on myogenin and myosin heavy chain (MHC) cellular localization in differentiated C2C12

cells. Cells were exposed to 1 nM or 10 nM of synthetic ($1\alpha,25(\text{OH})_2\text{D}_3$) or natural $1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 4 days. Cells were fixed, unspecific sites were blocked and incubated with anti-myogenin and anti-MHC antibodies as was described in Experimental. The primary antibodies were recognized by fluorophore-conjugated secondary antibodies. Fluorescent micrographs, representatives from three independent experiments, reflect myogenin red stained, MHC green stained or both (merge). Magnification 400X.

Fig. 7. Solbone A as the synthetic hormone increases cellular mass at the onset of myoblast differentiation. Cells were exposed to 1 nM (A) or 10 nM

(B) of synthetic or natural $1\alpha,25(\text{OH})_2\text{D}_3$ or in their absence (control) for 2 and 4 days. Cell mass was calculated as described under Experimental. Data represented in bar graphs are expressed as percent of variation between treated conditions versus control referred to day 0 of differentiation. Values are the mean \pm S.D. of three independent experiments. Different letters indicate statistical differences among groups for each day (ANOVA - Bonferroni $p < 0.05$).

Micrographs at phase-contrast microscopy represent effects on morphology of myoblast after 4 days of DMEM 2% HS differentiation induction. Images shown are representative from three independent experiments. Total magnification 400X. Bar = 50 μm .

Fig. 8. Solbone A as the synthetic hormone increases the Index Fusion at the onset of myoblast differentiation. Cells were exposed to 1 nM or 10 nM of synthetic or natural $1\alpha,25(\text{OH})_2\text{D}_3$ (Solbone A) or in their absence (control) for 4days. Cells were stained with MitoTracker Red and DAPI and index fusion was calculated as was described in Experimental. Data represented in bar graphs are the mean \pm S.D. of five independent experiments. Different letters indicate statistical differences among groups for each concentration (ANOVA - Bonferroni $p < 0.05$). Right panel, merge images of mitochondria (red stained) and nuclei (blue stained) are shown. Fluorescent micrographs are representative from three independent experiments. Total magnification 400X. Bar = 50 μm .
