A posteriori error estimates

ABSTRACT

In this paper we introduce an hp finite element method to solve a two-dimensional fluid–structure spectral problem. This problem arises from the computation of the vibration modes of a bundle of parallel tubes immersed in an incompressible fluid. We prove the convergence of the method and a priori error estimates for the eigenfunctions and the eigenvalues. We define an a posteriori error estimator of the residual type which can be computed locally from the approximate eigenpair. We show its reliability and efficiency by proving that the estimator is equivalent to the energy norm of the error up to higher order terms, the equivalence constant of the efficiency estimate being suboptimal in that it depends on the polynomial degree. We present an hp adaptive algorithm and several numerical tests which show the performance of the scheme, including some numerical evidence of exponential convergence.

1. Introduction

The goal of this paper is to introduce and analyze an hp finite element scheme for solving a fluid–structure interaction problem: the two-dimensional Laplace model for fluid–solid vibrations.

In recent decades, the numerical approximation of spectral problems arising in fluid mechanics has received increasing attention (see [1–6] and the references therein). In particular, the problem considered in this paper, which corresponds to approximating the vibrations of a bundle of tubes immersed in a fluid contained in a rigid cavity, has a considerable importance in nuclear engineering and has been studied by several authors (see, for example, [4,7,8]).

It is well known that adaptive procedures based on a posteriori error indicators play nowadays a relevant role in the numerical solution of partial differential equations. In particular, there are several papers concerning the development of a posteriori error estimates and efficient adaptive schemes for the h finite element approximation of different eigenvalue problems (see, for example, [9–13]). There are also some recent references regarding the hp finite element approximation of eigenvalue problems (see, for instance, [14–16]). However, the bibliography about hp adaptive

schemes for this kind of problems is scarce and mainly focused on electromagnetics (see, for instance, [17–19] for a survey on the application of the hp finite element method to electromagnetics, including eigenvalue problems).

On the other hand, the a posteriori error analysis for the hp version of the finite element method still presents several challenges even for source problems (see, for instance, [20–23] and the references therein). One of the main difficulties in hp adaptivity arises from the fact that the accuracy can be improved in two different ways, either by subdividing elements or by increasing the polynomial degree. There are different hp adaptive strategies. Some of them are based on the estimation of the local regularity of the solution (see, for example, [20,21,24,25]). Others follow the strategy developed by Demkowicz and co-workers (see [26–29] and the references therein) which uses the projection-based interpolation and a two-grid paradigm to design a self-adaptive hp finite element method. On the other hand, Melenk and Wohlmuth propose in [22] an hp strategy based on a predictor of the error in each element of the mesh.

In this paper we introduce and analyze an hp finite element approximation of the spectral problem described above. We obtain a priori error estimates and develop an a posteriori error estimator of the residual type which can be computed locally from the approximate eigenpair. We analyze the equivalence of this estimator with the energy norm of the error. In particular, we prove global reliability and local efficiency estimates, both up to higher order terms, the latter with a constant which depends on the

polynomial degree of the element. To the best of the authors' knowledge, simultaneous reliability and efficiency estimates, both with constants independent of the polynomial degree, have not been proved yet for any a posteriori error estimator for *hp* finite element methods. Nevertheless, the numerical experiments suggest that the proposed error indicator points out correctly the elements with largest error. Following the *hp* adaptive strategy given in [22], we propose an adaptive algorithm and apply it to different cavities and shapes of tubes. These numerical tests allow us to show the good performance of the error indicator and the adaptive algorithm, including an exponential rate of convergence in terms of the number of degrees of freedom.

The rest of the paper is organized as follows. In Section 2 we introduce the fluid–solid vibration problem. In Section 3 we present the *hp* finite element approximation and obtain a priori error estimates. In Section 4 we introduce the a posteriori error estimator and prove its equivalence with the energy norm of the error. In Section 5 we analyze some numerical aspects concerning the solution of the discrete generalized eigenvalue problem and introduce the adaptive refinement strategy. In Section 6 we report several numerical examples which allow assessing the performance of the adaptive scheme. Finally, we end the paper drawing some conclusions in Section 7.

2. The eigenvalue problem

We consider a coupled system composed of K elastically mounted parallel tubes immersed in a fluid inside a rigid cylindrical cavity. Our problem is to determine the vibration modes of the system.

Under reasonable assumptions (see [5]), the problem can be posed in a two-dimensional framework, a planar transverse section of the cylindrical cavity being its domain. Each tube is modeled as a harmonic oscillator with rigidity k and mass m and the fluid is taken as perfectly incompressible with density ρ .

Let $\Omega \subset \mathbb{R}^2$ be the bounded domain occupied by the fluid, which we assume polygonal. Let Γ_0 be its outer boundary and Γ_i , $i = 1, \dots, K$, the interfaces between each tube and the fluid. Let \mathbf{n} be the unit outer normal to the boundary of Ω (see Fig. 1).

The corresponding eigenvalue problem is the following one, which is known as the *Laplace Model* for fluid–solid vibrations [4,5,8]:

Find $\omega > 0$ (the vibration frequency) and $u \neq 0$ (the fluid pressure) such that

$$\begin{cases} \Delta u = 0 & \text{in } \Omega, \\ \frac{\partial u}{\partial n} = 0 & \text{on } \Gamma_0, \\ \frac{\partial u}{\partial n} = \frac{\rho\omega^2}{k-m\omega^2} \left(\int_{\Gamma_i} u \mathbf{n} \right) \cdot \mathbf{n} & \text{on } \Gamma_i, \quad i = 1, \dots, K. \end{cases} \quad (1)$$

Fig. 1. Sketch of the two-dimensional domain.

Let $\lambda := \rho\omega^2/(k - m\omega^2)$ and $\mathcal{V} := H^1(\Omega)/\mathbb{R}$ endowed with the H^1 -seminorm, which is a norm on \mathcal{V} . The variational problem associated with (1) reads as follows:

Find $\lambda \in \mathbb{R}$ and $u \in \mathcal{V}$ satisfying

$$\begin{cases} a(u, v) = \lambda b(u, v) \quad \forall v \in \mathcal{V}, \\ b(u, u) = 1, \end{cases} \quad (2)$$

where

$$a(u, v) := \int_{\Omega} \nabla u \cdot \nabla v \quad \text{and} \quad b(u, v) := \sum_{i=1}^K \left(\int_{\Gamma_i} u \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} v \mathbf{n} \right)$$

are continuous symmetric bilinear forms on \mathcal{V} , elliptic the former and non-negative the latter (i.e., $b(v, v) \geq 0 \forall v \in \mathcal{V}$).

The solution to (2) is given by a sequence of exactly $2K$ pairs (λ_j, u_j) , with positive eigenvalues that we assume to be increasingly ordered: $0 < \lambda_1 \leq \dots \leq \lambda_{2K}$ (see [5, Section II.2.1]). Associated to each one there is an eigenfunction $u_j \in \mathcal{V}$, such that $\{u_1, \dots, u_{2K}\}$ is a linearly independent set.

3. Finite element approximation and a priori error estimates

In this section we introduce an *hp* finite element method for the spectral problem described in the previous section, prove its convergence and obtain a priori error estimates for the eigenfunctions and the eigenvalues.

Let $\{\mathcal{T}_h\}$ be a family of triangulations of Ω such that any two triangles in \mathcal{T}_h share at most a vertex or an edge. Let h_T stand for the diameter of the triangle $T \in \mathcal{T}_h$. We assume that the family of triangulations $\{\mathcal{T}_h\}$ satisfies a minimum angle condition and, consequently, there exists a constant $\sigma > 0$ such that $h_T/r_T \leq \sigma$, where r_T is the diameter of the largest circle contained in T .

We associate with each element $T \in \mathcal{T}_h$ a (maximal) polynomial degree $p_T \in \mathbb{N}$. We assume that the polynomial degrees of neighboring elements are comparable, i.e., there exists a constant $\gamma > 0$ such that

$$\gamma^{-1} p_T \leq p_{T'} \leq \gamma p_T \quad \forall T, T' \in \mathcal{T}_h \text{ with } T \cap T' \neq \emptyset. \quad (3)$$

We denote $\mathbf{p} := \{p_T\}_{T \in \mathcal{T}_h}$, the family of polynomial degrees.

Throughout the paper, we will denote by C a generic positive constant, not necessarily the same at each occurrence, which may depend on the mesh and the degree of the polynomials, only through the parameters σ and γ , respectively.

We define the finite element space as follows:

$$\mathcal{V}_h^{\mathbf{p}} := \{v \in \mathcal{V} : v|_T \in \mathcal{P}_{p_T} \quad \forall T \in \mathcal{T}_h\},$$

where \mathcal{P}_k denotes the space of polynomials of degree at most k . Notice that the definition of $\mathcal{V}_h^{\mathbf{p}}$ allows for different maximal polynomial degrees on each edge of any triangle. Therefore, the space $\{v|_T : v \in \mathcal{V}_h^{\mathbf{p}}\}$ does not necessarily coincides with \mathcal{P}_{p_T} . However, there exists $p'_T \leq p_T$ such that

$$\mathcal{P}_{p'_T} \subset \{v|_T : v \in \mathcal{V}_h^{\mathbf{p}}\} \subset \mathcal{P}_{p_T} \quad (4)$$

and $p_T/p'_T \leq \gamma$ because of assumption (3).

The discrete eigenvalue problem associated with (2) is the following:

Find $\lambda_h \in \mathbb{R}$ and $u_h \in \mathcal{V}_h^{\mathbf{p}}$ satisfying

$$\begin{cases} a(u_h, v_h) = \lambda_h b(u_h, v_h) \quad \forall v_h \in \mathcal{V}_h^{\mathbf{p}}, \\ b(u_h, u_h) = 1. \end{cases} \quad (5)$$

This problem reduces to a generalized matrix eigenvalue problem. The theory in [5, Section II.2.1] holds also in this case and allows proving that this discrete problem attains $2K$ positive eigenvalues, which we assume increasingly ordered: $0 < \lambda_{h1} \leq \dots \leq \lambda_{h2K}$. Associated with each one, there is an eigenfunction $u_{hj} \in \mathcal{V}_h^{\mathbf{p}}$, such that $\{u_{h1}, \dots, u_{h2K}\}$ is a linearly independent set.

Our first goal is to prove that the solutions of the discrete eigenvalue problem (5) converge to those of the spectral problem (2). To do this, we will apply the classical spectral approximation theory from Babuška and Osborn [30]. With this purpose, we introduce the bounded linear operators $T, T_h^p : \mathcal{V} \rightarrow \mathcal{V}$ defined by

$$\begin{cases} f \in \mathcal{V} \mapsto Tf \in \mathcal{V}, \\ a(Tf, v) = b(f, v) \quad \forall v \in \mathcal{V}, \end{cases} \quad (6)$$

$$\begin{cases} f \in \mathcal{V} \mapsto T_h^p f \in \mathcal{V}_h^p \subset \mathcal{V}, \\ a(T_h^p f, v_h) = b(f, v_h) \quad \forall v_h \in \mathcal{V}_h^p. \end{cases} \quad (7)$$

The non-zero eigenvalues of T and T_h^p are the reciprocals of the eigenvalues of (2) and (5), respectively.

On the other hand, from the standard a priori estimate for the Neumann problem (see [31]), we know that the solution to problem (6) satisfies

$$Tf \in H^{1+r}(\Omega) \quad (8)$$

for all $r < \frac{\pi}{\theta}$, where θ is the largest reentrant angle of Ω and

$$\|Tf\|_{H^{1+r}(\Omega)/\mathbb{R}} \leq C \|f\|_{H^1(\Omega)}. \quad (9)$$

Consequently, the eigenfunctions of problem (2) also satisfy $u \in H^{1+r}(\Omega)$ for all $r < \frac{\pi}{\theta}$. Let us remark that for a polygonal domain Ω with at least one interface Γ_i , necessarily $\theta > \pi$ and consequently $\frac{1}{2} < \frac{\pi}{\theta} < 1$.

The following lemma allows us to conclude the convergence of T_h^p to T in norm as $\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T}$ goes to 0.

Lemma 3.1. For $r < \frac{\pi}{\theta}$, there exists a positive constant C such that, for all $f \in \mathcal{V}$,

$$\|Tf - T_h^p f\|_{H^1(\Omega)} \leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^r \|f\|_{H^1(\Omega)}.$$

Proof. By using standard arguments in hp error estimates (see [32, Theorem 2.1]; [33, Theorem 4.1]; [34, Lemma 4.5, Theorem 4.6]), it can be proved that there exists an operator $\Pi_h^p : H^{1+r}(\Omega) \rightarrow \mathcal{V}_h^p$ satisfying

$$\|v - \Pi_h^p v\|_{H^1(\Omega)} \leq C \left(\frac{h_T}{p_T} \right)^r \|v\|_{H^{1+r}(\Omega)/\mathbb{R}}$$

for all $T \in \mathcal{T}_h$, with a constant C independent of p_T' and h_T , where p_T' is as defined in (4). Now, from the definition of a and the fact that $\mathcal{V}_h^p \subset \mathcal{V}$, Cea's Lemma implies that, for all $f \in \mathcal{V}$,

$$\|Tf - T_h^p f\|_{H^1(\Omega)} \leq \|Tf - \Pi_h^p(Tf)\|_{H^1(\Omega)}.$$

Hence, since $p_T/p_T' \leq \gamma$, we obtain

$$\|Tf - T_h^p f\|_{H^1(\Omega)}^2 \leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^{2r} \|Tf\|_{H^{1+r}(\Omega)/\mathbb{R}}^2.$$

Thus, the result follows from (9). \square

As a consequence of the above lemma and the classical spectral approximation theory (see [30]) the eigenvalues and eigenfunctions of problem (5) converge to those of problem (2) as $\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T}$ goes to 0. From now on, we restrict our attention to a simple eigenvalue λ_j of problem (2) with corresponding eigenfunction u_j . Then, the j th eigenvalue of problem (5), λ_{hj} , converges to λ_j and the corresponding eigenfunction u_{hj} can be chosen so that u_{hj} converges to u_j , too.

In what follows we will adapt the techniques introduced in [35, Section 6.4] to obtain a priori error estimates for the approximate eigenvalues and eigenfunctions. Let us remark that we cannot use directly the results from this reference because the bilinear form b is not an inner product in our case.

Since the number of eigenvalues is finite ($2K$), the convergence of the discrete eigenvalues stated above immediately implies that there exist $\kappa > 0$ such that if $\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \leq \kappa$, then $\lambda_{hi} \neq \lambda_j$ for all $i \neq j$, $1 \leq i \leq 2K$. In such a case, we are allowed to define

$$\rho_{hj} := \max_{\substack{1 \leq i \leq 2K \\ i \neq j}} \frac{\lambda_j}{|\lambda_{hi} - \lambda_j|}.$$

Let P_h^p denote the \mathcal{V} -elliptic projection onto \mathcal{V}_h^p defined for any $w \in \mathcal{V}$ by

$$P_h^p w \in \mathcal{V}_h^p : a(P_h^p w - w, v_h) = 0 \quad \forall v_h \in \mathcal{V}_h^p. \quad (10)$$

The following lemma extends to our problem the results from Raviart and Thomas [35, Lemma 6.4-3].

Lemma 3.2. There exists $\kappa > 0$ such that, if $\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \leq \kappa$, then the discrete eigenfunction u_{hj} can be chosen so that

$$b(u_j - u_{hj}, u_j - u_{hj})^{1/2} \leq 2(1 + \rho_{hj}) b(u_j - P_h^p u_j, u_j - P_h^p u_j)^{1/2}. \quad (11)$$

Proof. We do not include the whole proof, since it follows closely the arguments used in [35] to prove Lemma 6.4-3. The main difference is that, in our case, the set of discrete eigenfunctions $\{u_{h1}, \dots, u_{h2K}\}$ is not a basis of \mathcal{V}_h^p . However, this linearly independent set can be chosen such that $b(u_{hi}, u_{hj}) = \delta_{ij}$, $1 \leq i, j \leq 2K$, and it can be completed to a basis $\{u_{h1}, \dots, u_{hN}\}$ ($N := \dim \mathcal{V}_h^p$), with the added basis functions satisfying

$$b(u_{hj}, v_h) = 0 \quad \forall v_h \in \mathcal{V}_h^p, j = 2K + 1, \dots, N.$$

Therefore, $b(u_{hi}, u_{hj}) = 0$ if $i \neq j$, $1 \leq i, j \leq N$. Using this basis, the proof of Lemma 6.4-3 from Raviart and Thomas [35] can be conveniently adapted to obtain (11). \square

Now we are in a position to prove the following a priori error estimates assuming that λ_j is a simple eigenvalue.

Proposition 3.1. For all $r < \frac{\pi}{\theta}$, there exist positive constants C and κ , such that, if $\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} < \kappa$, then

$$\|u_j - u_{hj}\|_{H^1(\Omega)} \leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^r, \quad (12)$$

$$b(u_j - u_{hj}, u_j - u_{hj})^{1/2} \leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^r \|u_j - u_{hj}\|_{H^1(\Omega)}, \quad (13)$$

$$|\lambda_j - \lambda_{hj}| \leq C \|u_j - u_{hj}\|_{H^1(\Omega)}^2. \quad (14)$$

Proof. The estimate (12) is a direct consequence of Lemma 3.1 and the classical spectral approximation theory (see [30]).

To prove (13), we use Lemma 3.2 and a duality argument to estimate the right-hand side of (11). Let $\varphi \in \mathcal{V}$ be the solution to

$$a(\psi, \varphi) = b(\psi, u_j - P_h^p u_j) \quad \forall \psi \in \mathcal{V}. \quad (15)$$

Hence, φ satisfies

$$\begin{cases} \Delta \varphi = 0 & \text{in } \Omega, \\ \frac{\partial \varphi}{\partial n} = 0 & \text{on } \Gamma_0, \\ \frac{\partial \varphi}{\partial n} = \mathbf{c}_i \cdot \mathbf{n} & \text{on } \Gamma_i, \quad i = 1, \dots, K \end{cases}$$

with $\mathbf{c}_i := \int_{\Gamma_i} (u_j - P_h^p u_j) \mathbf{n}$. The same arguments leading to (8) and (9) allow us to conclude that $\varphi \in H^{1+r}(\Omega)$ and

$$\begin{aligned} \|\varphi\|_{H^{1+r}(\Omega)/\mathbb{R}} &\leq C \left(\sum_{i=1}^K |\mathbf{c}_i|^2 |\Gamma_i| \right)^{1/2} \\ &\leq C b(u_j - P_h^p u_j, u_j - P_h^p u_j)^{1/2}, \end{aligned} \quad (16)$$

where, for the first inequality, we have used on each straight segment γ of Γ_i that $\|\mathbf{c}_i \cdot \mathbf{n}\|_{H^{1/2}(\gamma)} = \|\mathbf{c}_i \cdot \mathbf{n}\|_{L^2(\gamma)} \leq |\mathbf{c}_i|^2 |\gamma|$, because $\mathbf{c}_i \cdot \mathbf{n}$ is constant on γ .

Taking $\psi = u_j - P_h^p u_j$ in (15) and using (10), we obtain

$$\begin{aligned} b(u_j - P_h^p u_j, u_j - P_h^p u_j) &= a(u_j - P_h^p u_j, \varphi) \\ &= a(u_j - P_h^p u_j, \varphi - \Pi_h^p \varphi) \\ &\leq |u_j - P_h^p u_j|_{H^1(\Omega)} |\varphi - \Pi_h^p \varphi|_{H^1(\Omega)}, \end{aligned} \quad (17)$$

where Π_h^p is the same operator used in the proof of Lemma 3.1, which satisfies

$$|\varphi - \Pi_h^p \varphi|_{H^1(\Omega)}^2 \leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^{2r} \|\varphi\|_{H^{1+r}(\Omega)/\mathbb{R}}^2. \quad (18)$$

Then, (13) follows from (11), (17), (18) and (16), together with the inequality $|u_j - P_h^p(u_j)|_{H^1(\Omega)} \leq |u_j - u_{hj}|_{H^1(\Omega)}$, which holds because P_h^p is the projector onto \mathcal{V}_h^p .

Finally (14) follows from (12), (13) and the well known identity (see, for instance, Lemma 9.1 from [30])

$$\lambda_{hj} - \lambda_j = a(u_{hj} - u_j, u_{hj} - u_j) - \lambda_j b(u_{hj} - u_j, u_{hj} - u_j).$$

Thus we conclude the proof. \square

4. A posteriori error estimator

In this section we introduce an a posteriori estimator for the error in the energy norm of the approximate eigenfunction and prove its reliability and efficiency. From now on we drop the subindex j in λ_j , λ_{hj} , u_j and u_{hj} .

We introduce some notation that we will use in the definition and analysis of the error estimator. For any $T \in \mathcal{T}_h$ let \mathcal{E}_T denote the set of edges of T and $\mathcal{E} := \bigcup_{T \in \mathcal{T}_h} \mathcal{E}_T$. We decompose \mathcal{E} into disjoint sets $\mathcal{E}_{\Gamma_i} := \{\ell \in \mathcal{E} : \ell \subset \Gamma_i\}$, $0 \leq i \leq K$, and $\mathcal{E}_\Omega := \mathcal{E} \setminus \bigcup_{i=0}^K \mathcal{E}_{\Gamma_i}$.

For each $\ell \in \mathcal{E}_\Omega$ we choose a unit normal vector \mathbf{n}_ℓ and denote the two triangles sharing this edge T_{in} and T_{out} , with \mathbf{n}_ℓ pointing outwards T_{in} . For $v_h \in \mathcal{V}_h$ we set

$$\llbracket \frac{\partial v_h}{\partial \mathbf{n}} \rrbracket_\ell := \nabla(v_h|_{T_{out}}) \cdot \mathbf{n}_\ell - \nabla(v_h|_{T_{in}}) \cdot \mathbf{n}_\ell,$$

which corresponds to the jump of the normal derivative of v_h across the edge ℓ . Notice that this value is independent of the chosen direction of the normal vector \mathbf{n}_ℓ .

From (2) and (5), we know that for any $v_h \in \mathcal{V}_h^p$ the error $e := u - u_h$ satisfies

$$\int_\Omega \nabla e \cdot \nabla v_h = \sum_{i=1}^K \left(\lambda \int_{\Gamma_i} \mathbf{u} \mathbf{n} - \lambda_h \int_{\Gamma_i} u_h \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} v_h \mathbf{n} \right). \quad (19)$$

On the other hand, for any $v \in \mathcal{V}$, using (2) and integrating by parts we obtain

$$\int_\Omega \nabla e \cdot \nabla v = \sum_{i=1}^K \lambda \left(\int_{\Gamma_i} \mathbf{u} \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} v \mathbf{n} \right) + \sum_{T \in \mathcal{T}_h} \int_T \Delta u_h v + \sum_{T \in \mathcal{T}_h} \int_{\partial T} \frac{\partial u_h}{\partial \mathbf{n}} v.$$

Hence, defining for each edge $\ell \in \mathcal{E}$

$$J_\ell := \begin{cases} \frac{1}{2} \llbracket \frac{\partial u_h}{\partial \mathbf{n}} \rrbracket_\ell, & \ell \in \mathcal{E}_\Omega, \\ \frac{\partial u_h}{\partial \mathbf{n}}, & \ell \in \mathcal{E}_{\Gamma_0}, \\ \frac{\partial u_h}{\partial \mathbf{n}} - \left(\int_{\Gamma_i} \lambda_h u_h \mathbf{n} \right) \cdot \mathbf{n}, & \ell \in \mathcal{E}_{\Gamma_i}, \quad i = 1, \dots, K, \end{cases}$$

straightforward computations allow us to write, for all $v \in \mathcal{V}$,

$$\begin{aligned} \int_\Omega \nabla e \cdot \nabla v &= \sum_{T \in \mathcal{T}_h} \left(\int_T \Delta u_h v + \sum_{\ell \in \mathcal{E}_T} \int_\ell J_\ell v \right) \\ &\quad + \sum_{i=1}^K \left(\lambda \int_{\Gamma_i} \mathbf{u} \mathbf{n} - \lambda_h \int_{\Gamma_i} u_h \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} v \mathbf{n} \right). \end{aligned} \quad (20)$$

For each element $T \in \mathcal{T}_h$, we define the local error indicator η_T by

$$\eta_T^2 := \frac{h_T^2}{p_T^2} \|\Delta u_h\|_{L^2(T)}^2 + \sum_{\ell \in \mathcal{E}_T} \frac{|\ell|}{p_\ell} \|J_\ell\|_{L^2(\ell)}^2 \quad (21)$$

with $p_\ell := \max\{p_T : \ell \in \mathcal{E}_T\}$, and the global error estimator η_Ω by

$$\eta_\Omega^2 := \sum_{T \in \mathcal{T}_h} \eta_T^2.$$

To compare the error and the estimator we will use an hp Clément interpolation operator $I_h^p : \mathcal{V} \rightarrow \mathcal{V}_h^p$ defined in [22]. In this reference it is shown that this operator satisfies the following error estimates:

$$\|u - I_h^p u\|_{L^2(T)} \leq C \frac{h_V}{p_V} |u|_{H^1(\omega_V^4)} \quad \forall T \in \mathcal{T}_h : T \subset \omega_V^1, \quad (22)$$

$$\|u - I_h^p u\|_{L^2(\ell)} \leq C \left(\frac{h_V}{p_V} \right)^{\frac{1}{2}} |u|_{H^1(\omega_V^4)} \quad \forall \ell \in \mathcal{E}_V, \quad (23)$$

where, for each vertex V of the triangulation \mathcal{T}_h ,

$$\omega_V^0 := \{V\},$$

$$\omega_V^j := \bigcup \left\{ T \in \mathcal{T}_h : T \cap \omega_V^{j-1} \neq \emptyset \right\}, \quad j \geq 1,$$

$$h_V := \max \{h_T : V \text{ is a vertex of } T\},$$

$$p_V := \max \{p_T + 1 : V \text{ is a vertex of } T\},$$

$$\mathcal{E}_V := \{\ell \in \mathcal{E} : V \text{ is an endpoint of } \ell\}.$$

We observe in the estimates above that the subdomain ω_V^4 is larger than the one appearing in the error estimates for the classical h Clément interpolant. However this will only affect the size of the constants in the estimates.

The following theorem provides an upper bound for the error, which proves the reliability of the error estimator up to higher order terms.

Theorem 4.1. *There exists a positive constant C such that*

$$|e|_{H^1(\Omega)} \leq C \left[\eta_\Omega + \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^{2r} |e|_{H^1(\Omega)} \right].$$

Proof. By using the error equation (19) with $v_h = I_h^p e$ and (20) with $v = e - I_h^p e$, we obtain

$$\begin{aligned} |e|_{H^1(\Omega)}^2 &= \int_\Omega \nabla e \cdot \nabla (e - I_h^p e) + \int_\Omega \nabla e \cdot \nabla (I_h^p e) \\ &= \sum_{T \in \mathcal{T}_h} \left[\int_T \Delta u_h (e - I_h^p e) + \sum_{\ell \in \mathcal{E}_T} \int_\ell J_\ell (e - I_h^p e) \right] \\ &\quad + \sum_{i=1}^K \left(\lambda \int_{\Gamma_i} \mathbf{u} \mathbf{n} - \lambda_h \int_{\Gamma_i} u_h \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} e \mathbf{n} \right). \end{aligned}$$

Next, we estimate separately the two terms on the right-hand side above.

For each $T \in \mathcal{T}_h$, let V_T be one of the vertices of T and for each edge $\ell \in \mathcal{E}$ let V_ℓ be one of the endpoints of ℓ . Then, by using the Cauchy-Schwartz inequality, (22), (23), the definition of η_Ω and the fact that the triangulation satisfies the minimum angle condition and (3), we obtain

$$\begin{aligned} \sum_{T \in \mathcal{T}_h} \left[\int_T \Delta u_h (e - I_h^p e) + \sum_{\ell \in \mathcal{E}_T} \int_\ell J_\ell (e - I_h^p e) \right] \\ \leq C \sum_{T \in \mathcal{T}_h} \left[\frac{h_{V_T}}{p_{V_T}} \|\Delta u_h\|_{L^2(T)} |e|_{H^1(\omega_{V_T}^4)} + \sum_{\ell \in \mathcal{E}_T} \left(\frac{h_{V_\ell}}{p_{V_\ell}} \right)^{\frac{1}{2}} \|J_\ell\|_{L^2(\ell)} |e|_{H^1(\omega_{V_\ell}^4)} \right] \\ \leq C \eta_\Omega |e|_{H^1(\Omega)}. \end{aligned}$$

On the other hand, since $b(u, u) = 1$ and $b(u_h, u_h) = 1$, we have

$$\begin{aligned} & \sum_{i=1}^K \left(\lambda \int_{\Gamma_i} \mathbf{u} \mathbf{n} - \lambda_h \int_{\Gamma_i} \mathbf{u}_h \mathbf{n} \right) \cdot \left(\int_{\Gamma_i} \mathbf{e} \mathbf{n} \right) \\ &= \lambda b(u, u) - (\lambda + \lambda_h) b(u, u_h) + \lambda_h b(u_h, u_h) \\ &= (\lambda + \lambda_h) - (\lambda + \lambda_h) b(u, u_h) = \frac{\lambda + \lambda_h}{2} b(u - u_h, u - u_h) \\ &\leq C \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^{2r} |e|_{H^1(\Omega)}^2, \end{aligned}$$

where we have used (13) for the last inequality. Thus we conclude the proof. \square

In order to guarantee that the error indicator is efficient to guide an adaptive refinement scheme, our next goal is to prove that η_T is bounded by the H^1 norm of the error on a neighborhood of T , up to higher order terms.

For $T \in \mathcal{T}_h$, let b_T be the standard cubic bubble given by

$$b_T := \begin{cases} \lambda_1^T \lambda_2^T \lambda_3^T & \text{in } T, \\ 0 & \text{in } \Omega \setminus T, \end{cases}$$

where λ_1^T , λ_2^T and λ_3^T denote the barycentric coordinates of T .

For $\ell \in \mathcal{E}_\Omega$, we denote by T_1 and T_2 the two triangles sharing ℓ and we enumerate the vertices of T_1 and T_2 so that the vertices of ℓ are numbered first. Then we consider the piecewise quadratic edge bubble function b_ℓ defined by

$$b_\ell := \begin{cases} \lambda_1^{T_1} \lambda_2^{T_1} & \text{in } T_i, \quad i = 1, 2, \\ 0 & \text{in } \Omega \setminus T_1 \cup T_2. \end{cases}$$

The following lemma provides an upper estimate for the first term in the definition of η_T (cf. (21)).

Lemma 4.1. *There exists a positive constant C such that*

$$\frac{h_T}{p_T} \|\Delta u_h\|_{L^2(T)} \leq C p_T |e|_{H^1(T)}. \quad (24)$$

Proof. Using (20) with $v = \Delta u_h b_T \in H_0^1(T) \subset \mathcal{V}$, we obtain

$$\int_T (\Delta u_h)^2 b_T = \int_T \nabla e \cdot \nabla (\Delta u_h b_T) \leq C \frac{p_T}{h_T} |e|_{H^1(T)} \left[\int_T (\Delta u_h)^2 b_T \right]^{1/2},$$

where we have applied to $\Delta u_h b_T \in \mathcal{P}_{p_T+1}$, an inverse inequality proved in [22] (see Eq. (24) from this reference). Hence, using Eq. (22) from Melnik and Wohlmuth [22], we obtain

$$\|\Delta u_h\|_{L^2(T)} \leq C p_T \left[\int_T (\Delta u_h)^2 b_T \right]^{1/2} \leq C \frac{p_T^2}{h_T} |e|_{H^1(T)},$$

from which we conclude the proof. \square

Next, we prove an upper estimate for the second term in the definition of η_T (cf. (21)).

Lemma 4.2. *For all $\delta > 0$, there exists a positive constant C_δ such that, if $\ell \in \mathcal{E}_\Omega \cup \mathcal{E}_{\Gamma_0}$, then*

$$\frac{|\ell|^{1/2}}{p_\ell^{1/2}} \|J_\ell\|_{L^2(\ell)} \leq C_\delta p_\ell^{1+\delta} |e|_{H^1(\omega_\ell)} \quad (25)$$

and, if $\ell \in \mathcal{E}_{\Gamma_i}$, $1 \leq i \leq K$, then

$$\frac{|\ell|^{1/2}}{p_\ell^{1/2}} \|J_\ell\|_{L^2(\ell)} \leq C_\delta \left[p_\ell^{1+\delta} |e|_{H^1(\omega_\ell)} + p_\ell^\delta |\ell| \left| \int_{\Gamma_i} (\lambda u - \lambda_h u_h) \mathbf{n} \right| \right], \quad (26)$$

where $\omega_\ell := \cup\{T \in \mathcal{T}_h : \ell \in \mathcal{E}_T\}$.

Proof. We follow the arguments proposed in [22]. According to Lemma 2.4 from this reference, for all $\beta > 0$ there exists $C_\beta > 0$, only depending on β , such that

$$\|J_\ell\|_{L^2(\ell)} \leq C_\beta p_\ell^\beta \left(\int_\ell b_\ell^2 J_\ell^2 \right)^{1/2}. \quad (27)$$

Moreover, using Lemma 2.6 from the same reference [22] and standard scaling arguments, we have that for all $\beta > \frac{1}{2}$, there exists another constant $C_\beta > 0$, again depending only on β , such that for all $\epsilon > 0$, there exists $v_\epsilon \in H_0^1(\omega_\ell)$ satisfying

$$v_\epsilon|_\ell = b_\ell^2 J_\ell, \quad (28)$$

$$\|v_\epsilon\|_{L^2(\omega_\ell)}^2 \leq C_\beta \epsilon |\ell| \int_\ell b_\ell^2 J_\ell^2, \quad (29)$$

$$|v_\epsilon|_{H^1(\omega_\ell)}^2 \leq C_\beta \left[\epsilon p_\ell^{2(2-\beta)} + \epsilon^{-1} \right] \frac{1}{|\ell|} \int_\ell b_\ell^2 J_\ell^2. \quad (30)$$

For $\ell \in \mathcal{E}_\Omega \cup \mathcal{E}_{\Gamma_0}$, we use (20) with $v = v_\epsilon$ to write

$$\int_{\omega_\ell} \nabla e \cdot \nabla v_\epsilon = \int_{\omega_\ell} \Delta u_h v_\epsilon + \int_\ell J_\ell v_\epsilon.$$

Hence, using (28), (30), (29) and (24), we obtain

$$\begin{aligned} \int_\ell b_\ell^2 J_\ell^2 &= \int_\ell J_\ell v_\epsilon \leq |e|_{H^1(\omega_\ell)} |v_\epsilon|_{H^1(\omega_\ell)} + \|\Delta u_h\|_{L^2(\omega_\ell)} \|v_\epsilon\|_{L^2(\omega_\ell)} \\ &\leq \frac{C_\beta}{|\ell|^{1/2}} \left[\epsilon p_\ell^{2(2-\beta)} + \epsilon^{-1} + \epsilon p_\ell^4 \right]^{1/2} |e|_{H^1(\omega_\ell)} \left(\int_\ell b_\ell^2 J_\ell^2 \right)^{1/2}. \end{aligned}$$

Choosing $\epsilon = p_\ell^{-2}$ in this estimate, we have

$$\left(\int_\ell b_\ell^2 J_\ell^2 \right)^{1/2} \leq C_\beta \frac{p_\ell}{|\ell|^{1/2}} |e|_{H^1(\omega_\ell)},$$

from which, taking $\beta = \frac{1}{2} + \delta$ and using (27), we obtain (25).

Next, for $\ell \in \mathcal{E}_{\Gamma_i}$, $i = 1, \dots, K$, we use (20) with $v = v_\epsilon$ to write

$$\begin{aligned} \int_{\omega_\ell} \nabla e \cdot \nabla v_\epsilon &= \int_{\omega_\ell} \Delta u_h v_\epsilon + \int_\ell J_\ell v_\epsilon + \left(\int_{\Gamma_i} \lambda u \mathbf{n} - \int_{\Gamma_i} \lambda_h u_h \mathbf{n} \right) \\ &\quad \cdot \left(\int_\ell v_\epsilon \mathbf{n}_\ell \right). \end{aligned}$$

Proceeding as in the previous case, we obtain now

$$\left(\int_\ell b_\ell^2 J_\ell^2 \right)^{1/2} \leq C_\beta \frac{p_\ell}{|\ell|^{1/2}} |e|_{H^1(\omega_\ell)} + |\ell|^{1/2} \left| \int_{\Gamma_i} (\lambda u - \lambda_h u_h) \mathbf{n} \right|,$$

from which (26) follows. Thus we conclude the proof. \square

Now we may conclude the efficiency of the error indicator.

Theorem 4.2. *For all $\delta > 0$, there exists a positive constant C_δ such that for all $T \in \mathcal{T}_h$, if T has only inner edges (i.e., edges $\ell \in \mathcal{E}_\Omega$), then*

$$\eta_T \leq C_\delta p_T^{1+\delta} |e|_{H^1(\omega_T)}$$

and, if T has an edge lying on Γ_i , $i = 1, \dots, K$, then

$$\eta_T \leq C_\delta p_T^{1+\delta} \left[|e|_{H^1(\omega_T)} + \frac{h_T}{p_T} \left| \int_{\Gamma_i} (\lambda u - \lambda_h u_h) \mathbf{n} \right| \right],$$

where $\omega_T := \cup\{T' \in \mathcal{T}_h : T \text{ and } T' \text{ share an edge}\}$.

Proof. It is an immediate consequence of Lemmas 4.1 and 4.2 and the assumption (3). \square

Notice that the efficiency estimate above is suboptimal in that the equivalence constant depends on the polynomial degree. In contrast to the case of h refinement, it seems to be an open question whether uniform reliability and efficiency can be achieved for an hp a posteriori estimator. In fact, to the best of the authors'

knowledge, proofs of upper and lower bounds both independent of the polynomial degree have not been reported yet for any hp finite element method. Nevertheless, according to the experiments reported in Section 6, this seems to be just a theoretical issue. Indeed, the degrees achieved in the experiments are not that large, so that the factor $p_T^{1+\delta}$ can be considered bounded for practical purposes.

Remark 4.1. From Lemmas 4.1 and 4.2 we also obtain for all $\delta > 0$ the following global lower error estimate:

$$\eta_\Omega \leq C_\delta (\max \mathbf{p})^{1+\delta} \left(|e|_{H^1(\Omega)}^2 + \text{h.o.t.} \right)^{1/2},$$

where

$$\begin{aligned} \text{h.o.t.} &:= \sum_{i=1}^K \left[\sum_{T \in \mathcal{T}_i} \frac{|\ell|^2}{p_T^2} \left| \int_{\Gamma_i} (\lambda u - \lambda_h u_h) \mathbf{n} \right|^2 \right] \\ &\leq \frac{2}{\min \mathbf{p}} \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right) \sum_{i=1}^K |\Gamma_i| \left[|\lambda|^2 \left| \int_{\Gamma_i} (u - u_h) \mathbf{n} \right|^2 + |\lambda - \lambda_h|^2 \left| \int_{\Gamma_i} u_h \mathbf{n} \right|^2 \right]. \end{aligned}$$

Thus, from (13), (14) and the fact that $b(u_h, u_h) = 1$, we have

$$\text{h.o.t.} \leq \frac{2}{\min \mathbf{p}} \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right) \sum_{i=1}^K |\Gamma_i| \left[|\lambda|^2 \left(\max_{T \in \mathcal{T}_h} \frac{h_T}{p_T} \right)^{2r} |e|_{H^1(\Omega)}^2 + |e|_{H^1(\Omega)}^4 \right],$$

which is clearly a higher order term as compared with $|e|_{H^1(\Omega)}^2$.

5. Numerical aspects

In this section we analyze numerical aspects concerning the solution of the discrete problem (5) and introduce an adaptive refinement strategy based on the indicators η_T .

5.1. Solution of the generalized eigenvalue problem

The finite element space used for the discretization is $\mathcal{W}_h^{\mathbf{p}} = \mathcal{W}_h^{\mathbf{p}} / \mathbb{R}$ with

$$\mathcal{W}_h^{\mathbf{p}} := \left\{ v \in H^1(\Omega) : v|_T \in \mathcal{P}_{p_T} \quad \forall T \in \mathcal{T}_h \right\}.$$

We denote by \mathcal{N} the set of nodes of $\mathcal{W}_h^{\mathbf{p}}$ and decompose this set as follows: $\mathcal{N} = \mathcal{N}_1 \cup \mathcal{N}_2$, with \mathcal{N}_1 being the subset of nodes lying on $\bigcup_{i=1}^K \Gamma_i$ and \mathcal{N}_2 the subset of the remaining ones (i.e., those lying either in Ω or on Γ_0). We denote by N_i the number of nodes on \mathcal{N}_i , $i = 1, 2$.

Let

$$\mathbf{u}_1 := (u(P_i))_{P_i \in \mathcal{N}_1} \in \mathbb{R}^{N_1} \quad \text{and} \quad \mathbf{u}_2 := (u(P_i))_{P_i \in \mathcal{N}_2} \in \mathbb{R}^{N_2}.$$

To obtain a matrix form of the discrete problem (5), we write

$$\begin{pmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{pmatrix} \begin{pmatrix} \mathbf{u}_1 \\ \mathbf{u}_2 \end{pmatrix} = \lambda_h \begin{pmatrix} \mathbf{B}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{u}_1 \\ \mathbf{u}_2 \end{pmatrix} \quad (31)$$

with

$$\mathbf{A}_{rs} := (a(\beta_i, \beta_j))_{P_i \in \mathcal{N}_r, P_j \in \mathcal{N}_s}, \quad r, s = 1, 2,$$

$$\mathbf{B}_{11} := (b(\beta_i, \beta_j))_{P_i, P_j \in \mathcal{N}_1}$$

with $\{\beta_i\}_{P_i \in \mathcal{N}}$ being the nodal basis of $\mathcal{W}_h^{\mathbf{p}}$ (i.e., $\beta_i(P_j) = \delta_{ij}$).

The matrices on the left- and right-hand sides of (31) are symmetric and positive semi-definite. However, this eigenvalue problem is degenerate because the kernels of both matrices contain the vector $(1, \dots, 1)^t \in \mathbb{R}^{N_1+N_2}$. In fact, problems (5) and (31) are not equivalent, since the former is posed on the quotient space $\mathcal{W}_h^{\mathbf{p}} = \mathcal{W}_h^{\mathbf{p}} / \mathbb{R}$ and the latter on $\mathcal{W}_h^{\mathbf{p}}$. To obtain a matrix form of (5), it is enough to set to zero one arbitrary component, for instance of \mathbf{u}_2 . This is easily done by deleting in both matrices from (31)

the row and the column corresponding to the nodal component set to zero. Then, the resulting generalized eigenvalue problem is well posed because the matrix on the left-hand side is symmetric and positive definite. For simplicity we keep the same notation for the problem (31) with the corresponding row and column deleted.

Now, with the aim of reducing the computational cost, we proceed as follows. First, since the submatrix \mathbf{A}_{22} is invertible (indeed, symmetric and positive definite), by eliminating \mathbf{u}_2 from (31) we arrive at

$$\left(\mathbf{A}_{11} - \mathbf{A}_{12} \mathbf{A}_{22}^{-1} \mathbf{A}_{21} \right) \mathbf{u}_1 = \lambda_h \mathbf{B}_{11} \mathbf{u}_1. \quad (32)$$

Notice that although the matrix on the left-hand side of (32) is not sparse, its size is N_1 and, hence, significantly smaller than the size $N_1 + N_2 - 1$ of problem (31). Moreover, in actual computations, the matrix \mathbf{A}_{22}^{-1} is not explicitly computed. In fact, the columns of $\mathbf{A}_{22}^{-1} \mathbf{A}_{12}$ are obtained by solving N_1 linear systems with the same matrix $\mathbf{A}_{22} \in \mathbb{R}^{(N_2-1) \times (N_2-1)}$, which is sparse, symmetric and positive definite.

As a second step, we compute a complete diagonalization of the matrix \mathbf{B}_{11} . As far as the mesh have no triangles with vertices lying on two different Γ_i , this matrix is block diagonal with K full diagonal blocks, the size of each one being the number of nodes lying on each Γ_i . Thus, any standard eigensolver for symmetric matrices (QR, for instance) can be conveniently used for each diagonal block. Since the rank of \mathbf{B}_{11} is $2K$, as a result of the diagonalization we obtain a diagonal matrix of the form

$$\mathbf{D} := \begin{pmatrix} \mathbf{D}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} \in \mathbb{R}^{N_1 \times N_1},$$

where $\mathbf{D}_{11} := \text{diag}\{\mu_1, \dots, \mu_{2K}\}$, with $\mu_j \neq 0$, $j = 1, \dots, 2K$, and an orthogonal matrix $\mathbf{Q} \in \mathbb{R}^{N_1 \times N_1}$ such that $\mathbf{Q}^t \mathbf{B}_{11} \mathbf{Q} = \mathbf{D}$.

Let $\mathbf{v} := \mathbf{Q}^t \mathbf{u}_1$ and $\mathbf{S} := \mathbf{Q}^t (\mathbf{A}_{11} - \mathbf{A}_{12} \mathbf{A}_{22}^{-1} \mathbf{A}_{21}) \mathbf{Q}$. Then, problem (32) is equivalent to the following one:

$$\begin{pmatrix} \mathbf{S}_{11} & \mathbf{S}_{12} \\ \mathbf{S}_{21} & \mathbf{S}_{22} \end{pmatrix} \begin{pmatrix} \mathbf{v}_1 \\ \mathbf{v}_2 \end{pmatrix} = \lambda_h \begin{pmatrix} \mathbf{D}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{v}_1 \\ \mathbf{v}_2 \end{pmatrix}.$$

Since \mathbf{S}_{22} is invertible, the last step consists in eliminating \mathbf{v}_2 from these equations to arrive at

$$\left(\mathbf{S}_{11} - \mathbf{S}_{12} \mathbf{S}_{22}^{-1} \mathbf{S}_{21} \right) \mathbf{v}_1 = \lambda_h \mathbf{D}_{11} \mathbf{v}_1,$$

which is a generalized eigenvalue problem of size $2K$, with both matrices symmetric and \mathbf{D}_{11} diagonal and positive definite. Thus, this is a well posed (and small) problem that can be efficiently solved by any standard eigensolver. Finally, the eigenvectors of (31) are easily recovered by successively solving

$$\mathbf{S}_{22} \mathbf{v}_2 = -\mathbf{S}_{21} \mathbf{v}_1, \quad \mathbf{u}_1 = \mathbf{Q} \mathbf{v} \quad \text{and} \quad \mathbf{A}_{22} \mathbf{u}_2 = -\mathbf{A}_{21} \mathbf{u}_1.$$

5.2. Adaptive refinement strategy

For an h finite element adaptive scheme, there are several strategies to determine which elements should be refined. A usual one is the following: all the triangles T with $\eta_T \geq \theta \eta_M$ are marked to be refined, where

$$\eta_M^2 := \frac{1}{\#\mathcal{T}_h} \sum_{T \in \mathcal{T}_h} \eta_T^2$$

and $\theta \in (0, 1)$ is a parameter which can be arbitrarily chosen.

Our hp adaptive algorithm uses this maximum strategy to mark the triangles to be refined, with the additional consideration that at each step, for each marked triangle, it has to be decided whether to perform a p refinement or an h refinement. In the case of p refinement, the degree p_T of the marked element is increased by one and

Table 1
Refinement algorithm.

```

If  $\eta_T^2 \geq \theta \eta_M^2$  then
  if  $\eta_T^2 \geq (\eta_T^{\text{pred}})^2$  then
    subdivide  $T$  into four triangles  $T'_j$ ,  $1 \leq j \leq 4$ 
    longest edge strategy to maintain mesh conformity
     $p_{T'_j} := p_T$ 
     $(\eta_{T'_j}^{\text{pred}})^2 := \gamma_h \left(\frac{|T'_j|}{|T|}\right)^{p_T+1} \eta_T^2$ 
  else
     $p_{T'_j} := p_T + 1$ 
     $(\eta_{T'_j}^{\text{pred}})^2 := \gamma_p \eta_T^2$ 
  end
else
   $(\eta_T^{\text{pred}})^2 := \gamma_n (\eta_T^{\text{pred}})^2$ 
end
    
```

the triangle is kept fixed. On the other hand, in the case of h refinement, the marked element T is subdivided into four triangles, $T = \bigcup_{j=1}^4 T'_j$, and the degree is kept fixed in the new elements, i.e., $p_{T'_j} = p_T$. Moreover, the conformity of the mesh is preserved by means of a longest edge subdivision strategy on the unrefined neighboring triangles (see [36]). Because of this, it happens that some elements not marked for h refinement, are subdivided anyway into two or three triangles. Thus, in general, we will have that $T = \bigcup_{j=1}^k T'_j$ with $k = 2, 3$ or 4 .

In order to decide whether to apply a p or an h refinement to a particular triangle, we follow the approach proposed in [22], which is based on the comparison of the current local estimated error with a prediction of this error obtained from the preceding step. If at the preceding step there was an h refinement leading to $T = \bigcup_{j=1}^k T'_j$, $k = 2, 3, 4$, then the prediction indicator is defined as follows:

$$(\eta_{T'_j}^{\text{pred}})^2 := \gamma_h \left(\frac{|T'_j|}{|T|}\right)^{p_T+1} \eta_T^2,$$

where γ_h is a control parameter to be determined. On the other hand, if at the preceding step there was a p refinement on the element T , then the prediction indicator is defined by

$$(\eta_{T'_j}^{\text{pred}})^2 := \gamma_p \eta_T^2,$$

where $\gamma_p \in (0, 1)$ is a reduction factor which is chosen arbitrarily. Finally, for elements neither p nor h refined at the preceding step,

$$(\eta_T^{\text{pred}})^2 := \gamma_n (\eta_T^{\text{pred}})^2,$$

where γ_n is a reduction or amplification factor also arbitrarily chosen. In all cases, we proceed to an h refinement of T when the error indicator η_T is larger than the prediction indicator η_T^{pred} and to a p refinement otherwise.

Altogether, we arrive at the algorithm shown in Table 1.

We set $\eta_T^{\text{pred}} := 0$ for all elements T on the initial triangulation, so that the first step is a purely h refinement on all elements. Notice that this ensures that no triangle will have vertices lying on two different T_i on subsequent meshes (recall that this is useful for the procedure proposed to solve the generalized eigenvalue problem).

6. Numerical examples

We present in this section some numerical results which allow us to assess the performance of the proposed hp adaptive refinement strategy.

In all the numerical examples the control parameters appearing in the algorithm, have been chosen as follows: $\theta = 0.75$, $\gamma_h = 16$, $\gamma_p = 0.3$ and $\gamma_n = 2$.

The color palette, used in the figures, indicates the polynomial degree of each element.

6.1. Two concentric cylindrical tubes

In this first test we have taken two concentric cylindrical tubes with inner radius R_i and outer radius R_o (see Fig. 2). The analytical solution written in polar coordinates (r, ϕ) is as follows:

$$\lambda_1 = \lambda_2 = \frac{1}{\pi} \frac{R_o^2 - R_i^2}{R_i^2 (R_o^2 + R_i^2)},$$

$$u_1 = \left(r + \frac{R_o^2}{r}\right) \cos \phi, \quad u_2 = \left(r + \frac{R_o^2}{r}\right) \sin \phi.$$

We have taken $R_i = 1$ and $R_o = 3$, so that the exact eigenvalue is $\lambda \approx 0.2546479$.

Notice that in this test we have a double eigenvalue, so that in principle it does not lie in the theoretical framework considered in the previous sections where we have assumed the eigenvalues to be simple. However, according to our experiments, the results hold true for multiple eigenvalues, too.

The mesh shown in Fig. 2 has been used to initiate the adaptive process with quadratic finite elements in all triangles.

Fig. 3 shows the meshes obtained with the adaptive hp algorithm corresponding to steps 7 and 12 of the refinement process. The eigenvalue obtained at this last step with 101,781 degrees of freedom is $\lambda_h = 0.2546478$.

Since in this test we know the analytical solution, we have used it to compute the so called *effectivity indices*:

$$\text{eff} := \frac{|e|_{H^1(\Omega)}}{\eta_\Omega}.$$

We report in Table 2 these indices at all the steps. The table also includes the total number of degrees of freedom N for each step. It can be seen from this table that the effectivity indices remain bounded above and below throughout the refinement process.

For the theoretical results, we have assumed that the domain occupied by the fluid is polygonal. However, in this example with analytical solution the presence of curved boundaries causes a domain approximation error which we have not taken into account in the analysis. In this case, we have modified the adaptive algorithm

Fig. 2. Concentric cylindrical tubes. Domain and initial mesh.

Fig. 3. Concentric cylindrical tubes. Refined meshes: steps 7 (left) and 12 (right).

Table 2
Concentric cylindrical tubes. Effectivity indices.

Step	N	eff
0	56	0.1115
1	133	0.1350
2	247	0.1403
3	452	0.1219
4	831	0.1419
5	1487	0.1938
6	2945	0.2155
7	5416	0.2621
8	10,444	0.2261
9	17,815	0.2320
10	32,278	0.2259
11	56,307	0.2430
12	101,781	0.2210

as follows: when a new vertex appears on the straight edges approximating a curved boundary, it was moved radially to the boundary. Note that the resulting family of meshes is not nested and, consequently, the error might increase.

6.2. Rhomboidal tube within a rectangular cavity

In this test we consider a rhomboidal tube with side length $2\sqrt{2}$ centered in a quadrilateral cavity of side length 8, as shown in Fig. 4.

Fig. 4. Rhomboidal tube. Domain and initial mesh.

In this example the fluid domain has reentrant angles at the vertices of the tube. Because of this, the vibration modes involve eigenfunctions which are singular at these four points.

The initial mesh, again with quadratic elements, is shown in Fig. 4. Fig. 5 shows the mesh at step 22. Fig. 6 shows a sequence of zooms of this mesh around one of the reentrant angles.

It has been shown in [37–39] that a proper combination of h and p refinement allows to obtain an exponential rate of convergence in terms of a fractional power of the number N of degrees of freedom in the finite element approximation. Fig. 7 shows a plot of $\log \eta_{\Omega}$ versus \sqrt{N} , which shows that the estimated error η_{Ω} behaves asymptotically in this test as follows: $\eta_{\Omega} \approx C \exp(-\alpha\sqrt{N})$.

No analytical solution is available in this case to verify if the actual error also attains such an exponential rate of convergence. To provide some numerical evidence of such a behavior, we have estimated the error of the computed eigenvalues by using as ‘exact’ a more accurate approximation obtained by an extrapolation procedure. To do this, we have used the fact that the computed eigenvalues are expected to converge with a double order and we have determined the parameters λ , κ and α in the model

$$\lambda_h = \lambda + \kappa e^{-2\alpha\sqrt{N}},$$

by means of a weighted least-squares fitting. The weights have been chosen so that the most precise computed values λ_h play the more significant role in the fitting. Thus, we have obtained a value

Fig. 5. Rhomboidal tube. Refined mesh: step 22.

Fig. 8. Rhomboidal tube. Error curve for the eigenvalue.

$\lambda = 0.07896$, which we have used to plot $\log|\lambda_h - \lambda|$ versus $N^{1/2}$. This plot is shown in Fig. 8, where a linear dependence can be clearly seen for sufficiently large values of N . This is coherent with the expected exponential decay of the error with respect to the number of degrees of freedom.

It should be noted that a convergence rate $\exp(-\alpha\sqrt{N})$ is obtained in this numerical test, rather than $\exp(-\alpha\sqrt[3]{N})$, which is typical for the hp version of the finite element method for source elliptic problems with piecewise analytic data in the presence of corner singularities (see [40]). Although only a few convergence results are known for eigenvalue problems (see [41], for instance), in principle a convergence rate $\exp(-\alpha\sqrt[3]{N})$ should be expected in this

problem too. However, our numerical experiments show an improved convergence rate. To understand the reason for this behavior is a subject of future research.

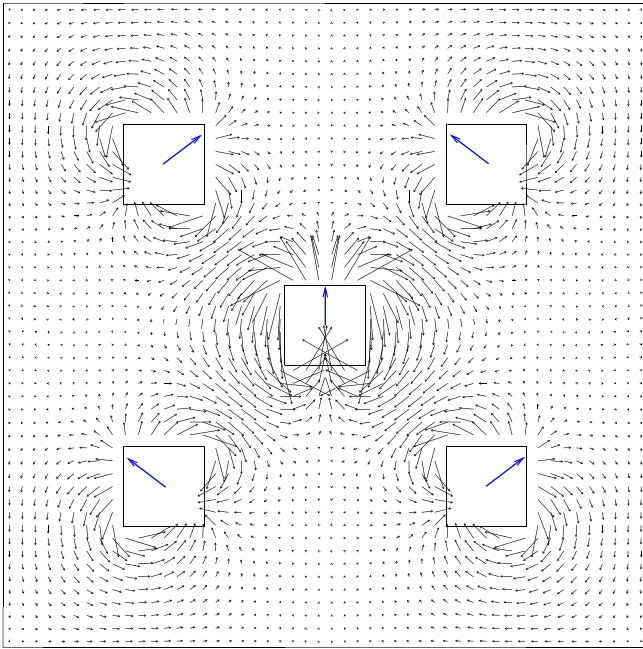

Fig. 11. Bundle of quadrilateral tubes. Computed fluid and tubes velocities.

6.3. A bundle of quadrilateral tubes

In this last example we have computed the main vibration mode (i.e., the mode with smallest eigenvalue) of a system closer to the actual applications: five square tubes immersed in a fluid occupying a rectangular cavity as shown in Fig. 9.

Fig. 10 shows the mesh obtained after eight steps of the hp adaptive scheme. Fig. 11 shows the fluid velocity field computed from the pressure obtained at the last step. The arrows at the center of each tube show the directions of the tubes motion.

7. Conclusions

An hp finite element method has been proposed to compute the free vibrations of a bundle of tubes immersed in an incompressible fluid contained in a rigid cavity. Convergence and a priori error estimates have been obtained for the hp finite element approximation of this spectral problem.

An a posteriori error indicator has been proposed and its reliability and efficiency have been rigorously proved. We have introduced an adaptive algorithm based on this indicator, which allows refining some of the elements and increasing the polynomial degree in others at each step.

The reported numerical experiments for different cavities and different shapes of tubes show the good performance of the error indicator and the adaptive scheme. Numerical evidence of the theoretically expected exponential convergence is also reported.
