Abstract: Bovine mastitis, the inflammation of the mammary gland, affects the quality and quantity of milk yield. Mastitis control relies on single or multiple combinations of antibiotic therapy. Due to increasing antibiotic resistance in pathogens, the intramammary infusion of lactic acid bacteria (LAB) has been considered as a potential alternative to antibiotics for treating and preventing bovine mastitis through the improvement of the host immunity. Probiotic effects are a strain-dependent characteristic; therefore, candidate LAB strains have to be evaluated efficiently to find out the ones with the best potential. Here, we investigated LAB strains originally isolated from feedlot cattle's environment regarding their ability in inducing the Toll-like receptor (TLR)-triggered inflammatory responses in bovine mammary epithelial (BME) cells in vitro. The BME cells were pre-stimulated with the LAB strains individually for 12, 24, and 48 h and then challenged with *Escherichia coli*-derived lipopolysaccharide (LPS) for 12 h. The mRNA expression of selected immune genes—interleukin 1 alpha (*IL-1α*), *IL-1β*, monocyte chemotactic protein 1 (*MCP-1*), *IL-8*, chemokine (C-X-C motif) ligand 2 (*CXCL2*), and *CXCL3* were quantified by real-time quantitative PCR (RT-qPCR). Results indicated that pretreatment with some *Lactobacillus* strains were able to differentially regulate the LPS inflammatory response in BME cells; however, strain-dependent differences were found. The most remarkable effects were found for *Lactobacillus acidophilus* CRL2074, which reduced the expression of *IL-1α*, *IL-1β*, *MCP-1*, *IL-8*, and *CXCL3*, whereas *Lactobacillus rhamnosus* CRL2084 diminished *IL-1β*, *MCP-1*, and *IL-8* expression. The pre-stimulation of BME cells with the CRL2074 strain resulted in the upregulated expression of three negative regulators of the TLRs, including the ubiquitin-editing enzyme A20 (also called tumor necrosis factor alpha-induced protein 3, TNFAIP3), single immunoglobulin IL-1

single receptor (SIGIRR), and Toll interacting protein (Tollip) after the LPS challenge. The CRL2084 pre-stimulation upregulated only Tollip expression. Our results demonstrated that the *L. acidophilus* CRL2074 strain possess remarkable immunomodulatory abilities against LPS-induced inflammation in BME cells. This *Lactobacillus* strain could be used as candidate for in vivo testing due to its beneficial effects in bovine mastitis through intramammary infusion. Our findings also suggest that the BME cells immunoassay system could be of value for the in vitro evaluation of the immunomodulatory abilities of LAB against the inflammation resulting from the intramammary infection with mastitis-related pathogens.

1. Introduction

Bovine mastitis is defined as the inflammation of the mammary gland, which greatly affects milk production, animal health and welfare, and economic profit of dairy worldwide [1]. Mastitis is caused due to infection by several of Gram-positive and Gram-negative bacteria, resulting in a varying degree of clinical signs ranging from asymptomatic sub-clinical infection to severe acute mammary gland inflammation [2,3]. Studies have shown that intramammary infection of *Escherichia coli* resulted in severe clinical illness that is characterized by an acute inflammation through the vigorous stimulation of cytokine and chemokine synthesis [4,5].

Due to the multiple bacterial etiology, the treatment regime for clinical mastitis mostly relies on antibiotic therapy to minimize the morbidity [6]. Prophylactic intramammary infusion of long-acting antibiotics is frequently practiced to prevent intramammary infection in a dry period known as “dry cow therapy” [7]. For both prophylactic and therapeutic cases, a single or a combination of multiple antibiotics can be prescribed. However, cure rate of mastitis depends on the species of mastitis-causing pathogens, the efficacy of antibiotics, as well as the host immune status [6,8]. It has been well documented that irrational antibiotic therapy often leads to the development of antimicrobial resistance that poses a severe threat to food animal health and production. Resistance to bovine mastitis can also cause significant public health hazards through the transmission of antibiotic-resistant bacterial pathogens as well as antibiotic residues through the consumption of raw milk of antibiotic-treated cows [9]. Because of the increased probability of transmission of antibiotic resistance genes to indigenous and potential pathogens through antibiotic therapy as well as the poor cure rates of mastitis during lactation [10,11], the conventional treatment method needs to be revisited, and innovative and sustainable therapeutic alternatives should be sought.

Probiotics, which are considered as generally recognized as safe (GRAS) microorganisms, are defined as “live microorganisms which when administered in adequate amounts confer a physiological health benefit on the host” [12]. Among probiotics, those that exert their beneficial effects through the modulation of the host immune system are termed as “immunobiotics” [13]. Several lactic acid bacteria (LAB) have probiotic/immunobiotic properties, although this is a strain-dependent characteristic. For the identification and selection of beneficial LAB strains that can be used as probiotics, there are some criteria recommended by international organizations [12]. For example, probiotics are generally host-specific and believed to be more effective in their natural habitat [14]. In addition, the beneficial effects of probiotics/immunobiotics should be scientifically demonstrated in the host or a host-related system towards which the probiotic is directed.

It has been reported that LAB located on teat epithelia, in bedding materials, or in milk are able exert probiotic effects [15,16]. Then, the intramammary infusion of probiotics has been proposed as one of the most promising alternatives for the prevention and control of bovine mastitis [17–23]. The adhesion to epithelial cells and colonization of the mucosal tissue, the competition for nutrients, as well as the production of antimicrobial compounds are major pathogen-inhibitory mechanisms of LAB when

administered into the bovine mammary gland [17]. In addition, the modulation of host immune response, in particular the capacity to differentially modulate the Toll-like receptor (TLR)-mediated innate immunity in mammary epithelia cells, is considered as one important characteristic of immunobiotic strains against mastitis [17].

Considering this background, the aim of this study was to select and characterize potential immunobiotic LAB strains that could be effectively used in the prevention or treatment of bovine mastitis. For this purpose, we took advantage of two scientific advances recently achieved by our research groups. On the one hand, we developed an immortalized bovine mammary epithelial (BME) cell line [24] and characterized it in terms of its ability to serve as a valuable in vitro tool for the study of the host–microbial interaction and the modulation of the mammary epithelial innate immunity triggered in response to infections. Our recent transcriptomic studies using the BME cells in vitro system have identified some potential immunological biomarkers for the evaluation of immunomodulatory probiotic candidates for the prevention or control bovine mastitis [25]. On the other hand, several LAB strains were isolated from the feedlot cattle environment [26] and characterized in terms of their potential probiotic properties. Among them, *Lactobacillus mucosae* CRL2069, *Lactobacillus acidophilus* CRL2074, *Lactobacillus fermentum* CRL2085, and *Lactobacillus rhamnosus* CRL2084 were reported to be free of transmissible antibiotic resistance genes and virulence factors, and capable of reaching a high number in in vitro culture media [27], indicating their optimal immunological potentials. Moreover, in a recent study, the ability of lactobacilli isolated from a feedlot cattle environment to differentially modulate the innate immune response triggered by TLR activation in bovine intestinal epithelial (BIE) cells was evaluated. Our results demonstrated that *L. mucosae* CRL2069 and *L. rhamnosus* CRL2084 had a remarkable capacity to modulate TLR4-mediated inflammation in BIE cells through the up-regulation of TLR-negative regulators, which in turn modulate the intracellular signaling pathways and reduce the expression of pro-inflammatory cytokines and chemokines [28]. We therefore aimed herein to further evaluate the ability of feedlot cattle lactobacilli to modulate the bovine mammary gland innate immunity triggered by *Escherichia coli* (*E. coli*)-derived lipopolysaccharide (LPS) using the BME cells in vitro system.

2. Results

2.1. Expression Dynamics of TLR2 and TLR4 in BME Cells after Ligand Stimulation

The development of innate immune responses against Gram-positive and Gram-negative bacterial infections is launched by the activation of TLR2 and TLR4, respectively. Thus, we first aimed to evaluate the expressions of *TLR2* and *TLR4* in BME cells in response to the ligands Pam3CSK4 and LPS. The Pam3CSK4 stimulation resulted in significant upregulation of *TLR2* expression in BME cells at 3 h, 6 h and 12 h post-stimulation (Figure 1). There was an increasing trend of *TLR2* expression in BME cells after LPS stimulation, but it was not statistically significant (Figure 1). Significant upregulation of *TLR4* expression was observed in BME cells at 12 and 24 h after stimulation with LPS. On the contrary, *TLR4* expression was not altered after the stimulation of BME cells with Pam3CSK4 (Figure 1).

Figure 1. Expression dynamics of Toll-like receptor 2 (*TLR2*) and Toll-like receptor 4 (*TLR4*) in bovine mammary epithelial (BME) cells after ligand stimulation. BME cells (2.5×10^5 cells/well) were stimulated with lipopolysaccharide (LPS) (1.0 $\mu\text{g}/\text{mL}$) or Pam3CSK4 (200 ng/mL) for 3, 6, 12, and 24 h. Then, mRNA expression of *TLR2* (A) and *TLR4* (B) were measured by RT-qPCR. Results presented are as mean \pm SD of three independent experiments. * $p < 0.05$ indicates significant difference against control.

2.2. Modulation of LPS-Induced Cytokine Expression in BME Cells by Lactobacilli

Taking into consideration that the duration of bacterial pre-stimulation is a determining factor for the epithelial cellular response, we performed experiments with three time points to evaluate the temporal effect of LAB pretreatment in preventing subsequent inflammatory challenge. For this purpose, BME cells were pre-stimulated with *L. mucosae* CRL2069, *L. acidophilus* CRL2074, *L. rhamnosus* CRL2084, *L. fermentum* CRL2085, or Pam3CSK4 for 12, 24, or 48 h, followed by a challenge with LPS for further 12 h. Then, mRNA expression of two proinflammatory cytokines—interleukin 1 alpha (*IL-1 α*) and *IL-1 β* —were measured by RT-qPCR (Figure 2). Results indicated that LPS challenge resulted in a significant augmentation of *IL-1 α* expression in BME cells as compared to untreated control cells. The pre-stimulation of BME cells with *L. acidophilus* CRL2074 for 12 h and *L. fermentum* CRL2085 for 48 h was able to reduce the LPS-induced expression of *IL-1 α* (Figure 2A). The pre-stimulation of Pam3CSK4 resulted in an upward trend of LPS-induced expression of *IL-1 α* in BME cells (Figure 2A). Similar to *IL-1 α* expression, the LPS challenge resulted in a significant increase of the expression of *IL-1 β* in BME cells. *L. acidophilus* CRL2074 and *L. rhamnosus* CRL2084 showed significant ability to reduce the expression of *IL-1 β* in LPS-challenged BME cells with 12 h of pre-stimulation (Figure 2B). In addition, the pre-stimulation with Pam3CSK4 resulted in upregulation of LPS-induced expression of *IL-1 β* in BME cells (Figure 2B).

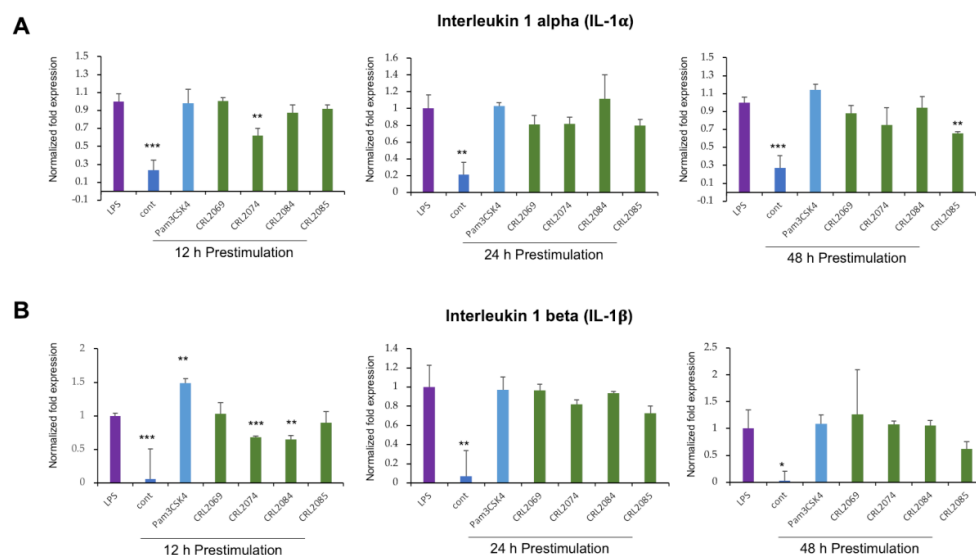

Figure 2. Evaluation of the immunomodulatory activity of feedlot cattle lactobacilli in bovine mammary epithelial (BME) cells. BME cells (2.5×10^5 cells/well) were pre-stimulated either with *Lactobacillus mucosae* CRL2069, or *Lactobacillus acidophilus* CRL2074, or *Lactobacillus rhamnosus* CRL2084, or *Lactobacillus fermentum* CRL2085, or Pam3CSK4 for 12, 24, or 48 h, followed by a challenge with lipopolysaccharides (LPS) for further 12 h. Then, mRNA expression of interleukin 1 alpha (*IL-1 α*) (A) and *IL-1 β* (B) were measured by RT-qPCR. Results presented are as mean \pm SD of three independent experiments. LPS, LPS-challenged cells without lactic acid bacteria (LAB) pre-stimulation; cont, untreated control cells; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ are the significant differences against LPS.

2.3. Modulation of LPS-Induced Neutrophil Chemoattractants in BME Cells by Lactobacilli

In order to evaluate the ability of the feedlot cattle *Lactobacillus* strains to modulate the chemotaxis of immune cells into the infected mammary gland, we estimated the expression dynamics of two selected neutrophil chemoattractants in BME cells. The BME cells were pre-stimulated with *L. mucosae* CRL2069, *L. acidophilus* CRL2074, *L. rhamnosus* CRL2084, *L. fermentum* CRL2085, or Pam3CSK4, followed by a challenge with LPS (Figure 3).

Interleukin 8 (IL-8), also known as chemokine (C-X-C motif) ligand 8 (CXCL8), is a chemoattractant and neutrophil activator. All the feedlot cattle lactobacilli evaluated here were able to significantly

reduce the LPS challenge-induced expression of *IL-8* in BME cells (Figure 3A). The pre-stimulation of BME cells for 24 h with Pam3CSK4 also reduced the LPS-induced *IL-8* expression in BME cells (Figure 3A).

The chemokine (C-X-C motif) ligand 2 (CXCL2), also called macrophage inflammatory protein 2 alpha (MIP-2 α), is a protein chemotactic factor for neutrophils. As shown in Figure 3B, only the pre-stimulation with *L. acidophilus* CRL2074 for 12 h was able to significantly reduce the expression of CXCL2 in LPS-challenged BME cells.

Figure 3. Evaluation of the immunomodulatory activity of lactobacilli in bovine mammary epithelial (BME) cells. BME cells (2.5×10^5 cells/well) were pre-stimulated either with *L. mucosae* CRL2069, or *L. acidophilus* CRL2074, or *L. rhamnosus* CRL2084, or *L. fermentum* CRL2085, or Pam3CSK4 for 12, 24, or 48 h, followed by a challenge with lipopolysaccharides (LPS) for further 12 h. Then, mRNA expression of interleukin 8 (IL-8) (A) and chemokine (C-X-C motif) ligand 2 (CXCL2) (B) were measured by RT-qPCR. Results presented are as mean \pm SD of three independent experiments. LPS, LPS-challenged cells without LAB pre-stimulation; cont, untreated control cells; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ are the significant differences against LPS.

2.4. Modulation of LPS-Induced Monocyte Chemoattractants in BME Cells by Lactobacilli

The monocyte chemotactic protein 1 (MCP-1), also known as chemokine (C-C motif) ligand 2 (CCL2), is one of the most important chemokines that controls the migration and infiltration of monocytes and macrophages into the infected tissues. The pre-stimulation of BME cells with *L. acidophilus* CRL2074 for 12 h or *L. rhamnosus* CRL2084 for 12 or 24 h minimized the LPS-induced expression of *MCP-1* (Figure 4A). Contrarily, though unexpected, the pre-stimulation with *L. mucosae* CRL2069 for 24 and 48 h resulted in upregulation of LPS-induced *MCP-1* expression in BME cells, similarly to Pam3CSK4 (Figure 4A). The expression of *MCP-1* in *L. fermentum* CRL2085-treated BME cells was also significantly lower than control cells after 24 h of pre-stimulation.

The chemokine (C-X-C motif) ligand 3 (CXCL3) or macrophage inflammatory protein 2 beta (MIP-2 β) controls the migration and adhesion of monocytes. The pre-stimulation with the four *L. mucosae* CRL2069, *L. acidophilus* CRL2074, *L. rhamnosus* CRL2084, and *L. fermentum* CRL2085 were able to reduce the LPS-induced expression of CXCL3 in BME cells (Figure 4B). Results indicated that CRL2074 and CRL2084 showed the most significant effects, and 12 h pre-stimulation showed stronger influence on immunomodulatory activities of LAB strains against LPS-induced inflammation (Figure 4B). However, 48 h of Pam3CSK4 pre-stimulation resulted in upregulation of the LPS-induced CXCL3 expression in BME cells (Figure 4B).

Figure 4. Evaluation of the immunomodulatory activity of lactobacilli in bovine mammary epithelial (BME) cells. BME cells (2.5×10^5 cells/well) were pre-stimulated either with *L. mucosae* CRL2069, or *L. acidophilus* CRL2074, or *L. rhamnosus* CRL2084, or *L. fermentum* CRL2085, or Pam3CSK4 for 12, 24, or 48 h, followed by a challenge with lipopolysaccharides (LPS) for further 12 h. Then, mRNA expression of monocyte chemotactic protein 1 (MCP-1) (A) and chemokine (C-X-C motif) ligand 3 (CXCL3) (B) were measured by RT-qPCR. Results presented are as mean \pm SD of three independent experiments. LPS, LPS-challenged cells without LAB pre-stimulation; cont, untreated control cells; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ are the significant differences against LPS.

2.5. Modulation of Negative Regulators of LPS-Induced Inflammation in BME Cells by Lactobacilli

Because two strains, *L. acidophilus* CRL2074 and *L. rhamnosus* CRL2084, exerted anti-inflammatory properties in LPS-challenged BME cells having a 12 h pre-stimulation, we further tested whether they were able to upregulate the expression of negative regulators of the TLR4 signaling pathway. The pre-stimulation of both *L. acidophilus* CRL2074 and *L. rhamnosus* CRL2084 resulted in increased expression of the negative regulators ubiquitin editing enzyme A20 (also called TNF alpha-induced protein 3 or TNFAIP3), single immunoglobulin IL-1 single receptor (SIGIRR), and Toll interacting protein (Tollip) in MBE cells (Figure 5). The expression of B cell lymphoma 3 (Bcl3) in LPS-challenged BME cells remained stable irrespective of LAB pre-stimulation (Figure 5A,B). The pre-stimulation of CRL2074 strain resulted in significant upregulation A20 Tollip at 3 h post-LPS challenge to BME cells (Figure 5A). Notably, the expressions of A20, SIGIRR, and Tollip were significantly upregulated in CRL2074 pretreated BME cells when they were challenged with LPS for 6 h (Figure 5B). The CRL2084 pre-stimulation resulted in no significant changes in expression of any of four factors tested after 3 h LPS challenge (Figure 5A), but resulted in an increased expression of Tollip after 6 h of LPS challenge (Figure 5B).

Figure 5. Evaluation of the immunomodulatory activity of lactobacilli in bovine mammary epithelial (BME) cells. BME cells (2.5×10^5 cells/well) were pre-stimulated either with *L. acidophilus* CRL2074 or *L. rhamnosus* CRL2084 for 12 h, followed by challenge with lipopolysaccharides (LPS) for further 3 h (A) or 6 h (B). Then, mRNA expression of A20, single immunoglobulin IL-1 single receptor (SIGIRR), Toll interacting protein (Tollip), and B cell lymphoma 3 (Bcl3) were measured by RT-qPCR. Results presented are as mean \pm SD of three independent experiments. LPS, LPS-challenged cells without LAB pre-stimulation; Control, untreated control cells; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ are the significant differences against LPS.

3. Discussion

The current mastitis control strategies in dairy farms largely involve either local intramammary infusion or parenteral administration of antibiotics. Indiscriminate antibiotic therapy to the lactating cow not only poses the risk of residual effect to humans through contaminated milk consumption, but also reduces the antibiotic efficacy due to emergence of antimicrobial-resistant mastitis pathogens [29]. The legal restrictions for using antibiotics in several developed countries as well as the continuous emergence of global antimicrobial resistant pathogens make imperative the exploration of effective substitutes for antibiotics. Several alternative approaches including the application of immunomodulatory beneficial microbes are being explored for preventing mastitis in dairy cows. It is known that *Lactobacillus* strains are diverse in their immunoregulatory properties, and therefore those properties need to be rigorously evaluated before the application of these live microorganisms into the bovine mammary gland. Moreover, even though lactobacilli are well known beneficial bacterial species and several strains are able to exert positive effects against subclinical bovine mastitis [20,21], it was recently reported in a murine model that the intramammary infusion of certain lactobacilli strains can be the cause of mastitis [19]. In this work, we presented a bovine mammary epithelial cells in vitro system that can be valuable for the selection and characterization of immunobiotic LAB intended for the prevention of mastitis. In addition, the present study evaluated the immunomodulatory potential of LAB strains isolated from dairy cattle environments on bovine mammary epithelial cells, and selected candidates that can be further studied in vivo.

The use of primary cells for in vitro investigation has the advantages of reflecting appropriate mitogenic responses as well as preserved physiological functions, including those related to the generation of immune responses. However, the isolation of epithelial cells from mammary gland tissue is costly, difficult, and allows only single and short-term experiments [30]. On the contrary, cell lines have advantages over primary cultures in that they are able to replicate for numerous passages, retaining reasonably constant cellular characteristics. The BME cell line used in the present study was cloned from the mammary tissue of a 200-day pregnant Holstein cow, and it was demonstrated that this cell line was able to respond to mitogenic stimulations [24]. Moreover, we recently reported

that the BME cell line has an epithelial-like morphology, expresses members of the TLR family, and is able to induce proinflammatory cytokine and chemokine responses after the stimulation with LPS or *S. aureus* [25]. In particular, LPS stimulation significantly upregulated the expression of cytokines (*IL-1 α* and *IL-1 β*) and chemokines (*IL-8*, *MCP-1*, *CXCL2*, and *CXCL3*) in BME cells [25]. In a similar approach, we have also demonstrated that the BME cell line is a useful tool for investigating the molecular interaction between host epithelial cells and pathogenic or beneficial microorganisms, in particular the mechanisms through which microorganisms modulate the host epithelial immune responses [31,32]. We therefore postulated that BME cells have the potential to be used in a similar way in order to evaluate the cellular and molecular interactions of microorganisms with bovine epithelial cells in the mammary gland, thereby providing an efficient in vitro selection tool for immunobiotic candidates against bovine mastitis.

The experiments carried out here were based on the hypothesis that feedlot cattle LAB strains are able to induce a certain degree of innate immune modulation in BME cells through their interaction with TLRs, and that the transcriptomic changes induced in the bovine cells by this interaction can inhibit or minimize the subsequent pathogen-induced inflammatory reaction. This approach has been useful for the selection of immunomodulatory LAB, as we have described previously for other porcine and bovine in vitro immunoassay systems [32–34]. Therefore, in the BME cells in vitro evaluation system, the cells were pre-stimulated with the different feedlot cattle LAB strains for a certain period and then challenged with a pathogen-derived bioactive molecule. It was reported that the duration of the bacterial pre-stimulation significantly affects the epithelial cellular immune responses [31,32,34]. Therefore, we performed experiments with three different periods (12, 24, and 48 h) of LAB pre-stimulations in order to evaluate the temporal effects of LAB pretreatment in the modulation of the subsequent inflammatory challenge. On the other hand, we selected LPS as the inflammatory challenge, taking into consideration that *E. coli* is one of the major mastitis-causing pathogens that induces acute inflammation of the mammary gland through the activation of the LPS/TLR4-mediated signaling pathway [4,5].

In our study, the most remarkable effects on the expressions of inflammatory factors were found when a period of 12 h was used to stimulate BME cells with feedlot cattle LAB strains, before the challenge with LPS. The expression of *IL-1 α* , *IL-1 β* , *MCP-1*, *CXCL2*, and *CXCL3* in BME cells were differentially modulated by at least one of the LAB strains after 12 h of pre-stimulation. On the other hand, both 12 and 24 h pre-stimulations markedly modulated *IL-8* expression. These results indicate that short contact times with LAB would be more efficient to achieve optimal immunomodulatory effects on the mammary gland epithelium in the context of TLR4-mediated inflammation. This finding contrasts with our previous results obtained in other porcine and bovine in vitro immunoassay systems. When immunomodulatory LAB strains were searched in BIE cells or porcine intestinal epithelial (PIE) cells, it was found that among the several pre-stimulation times evaluated, 48 h was the most appropriate time to obtain optimal modulation of epithelial inflammatory responses [31,33,34]. Some other related studies have also reported that prolonged stimulation times correlated with optimal immunomodulatory capacities for LAB strains in intestinal systems [35,36]. These differences found between the intestinal and the mammary gland in vitro systems may be related to the physiology of each mucosal tissue from which the epithelial cells derive. Intestinal epithelial cells, more adapted to being in contact with microorganisms, would require a longer period of contact to respond with transcriptomic changes that modify innate immune responses. On the other hand, mammary gland epithelial cells would be less adapted to be contact with microorganisms and therefore they would have a decreased tolerance to microbial molecules. These results presuppose practical limitations in the use of LAB in vivo in the bovine host, as it would be necessary to achieve a short stimulation time. However, it must be kept in mind that the epithelial cells of the mammary gland are immersed in a complex microenvironment and are influenced by various factors such as hormones, immune and non-immune cells, as well as microorganisms from the normal microbiota. In these circumstances, the immunomodulatory capacity of LABs could be modified and a longer stimulation period could be

necessary. Undoubtedly, *in vivo* kinetic studies would be of great value to optimize LAB treatments aimed at achieving optimal beneficial immunomodulatory effects in the bovine mammary gland.

As demonstrated for almost all probiotic properties, the ability of LAB to modulate the TLR4-mediated immune response in BME cells was a strain-dependent characteristic (Figure 6). Among the feedlot cattle lactobacilli evaluated in this work, *L. acidophilus* CRL2074 and *L. rhamnosus* CRL2084 showed the highest ability to differentially modulate the expression of proinflammatory cytokines and chemokines in LPS-challenged BME cells. *L. acidophilus* CRL2074 was able to reduce the expression of all the inflammatory factors evaluated with the exception of CXCL2, whereas *L. rhamnosus* CRL2084 reduced *IL-1 β* , *MCP-1*, and *IL-8*.

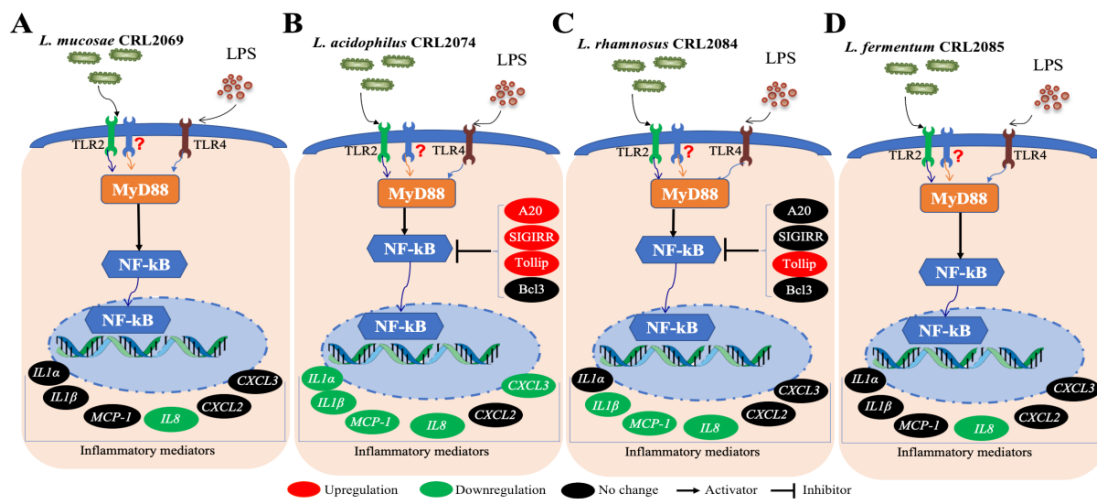

Figure 6. Proposed mechanism of LAB-mediated modulation of inflammatory responses in bovine mammary epithelial (BME) cells. Being Gram-positive bacteria, immunobiotic strains when pre-stimulated to BME cells were recognized by TLR2 and induced a downstream signaling cascade of NF κ B transcription activation through adaptor protein MyD88, initiating the secretion of cytokine and chemokine profiles. The LPS derived from *Escherichia coli*, when used to challenge the immunobiotic-sensitized BME cells, was recognized by TLR4 and followed the same pathway for NF κ B activation through MyD88, inducing inflammatory responses. Thus, having a strain-dependent variation, immunobiotic-mediated pre-activation of TLR2 might influence the subsequent TLR4-induced inflammation. *L. acidophilus* CRL2074 and *L. rhamnosus* CRL2084 showed the highest ability to differentially modulate the expression of proinflammatory cytokines and chemokines in LPS-challenged BME cells. In addition, several negative regulators of TLR signaling also influenced the resultant cytokine and chemokine profiles. The *L. acidophilus* CRL2074 pre-exposure was able to upregulate A20, SIGIRR, and Tollip expression, whereas *L. rhamnosus* CRL2084 only upregulated the expression of Tollip.

In intramammary gland infections, the invading bacteria start to multiply within the alveolus and liberate toxins that induce the release of inflammatory factors by epithelial cells and resident leukocytes, which attracts blood neutrophils and monocytes to the site of infection [37,38]. The recruitment and activation of immune cells is a hallmark response in the host–pathogen interaction during intramammary gland infections. A large influx of neutrophils occurs after the infectious challenge, and the concentration of those phagocytic cells in the infected tissue correspond to the inflammatory response intensity [4,39,40]. Although the phagocytic and microbicidal activity of neutrophils is important for limiting the infection and eliminating the pathogen, if this response is not properly regulated it can lead to local tissue damage, contributing to worsening the course of the disease [37,41]. Oxidant compounds and enzymes released by neutrophils result in mammary alveolar atrophy, epithelial damage, and breaching of the blood barrier, increasing the susceptibility to systemic

infection [37,38]. Thus, uncontrolled inflammation in the mammary gland can be harmful, even fatal, for the bovine host [42,43].

The modulation of cytokine and chemokine expression may offer novel approaches in the prevention or treatment of bovine mastitis [41]. In this regard, *L. acidophilus* CRL2074 significantly reduced the expression of *IL-1 α* , *IL-8*, *MCP-1*, and *CXCL3* in LPS-challenged BME cells. Pro-inflammatory cytokine *IL-1 α* is important to elicit an acute phase response of intramammary inflammation [38]. On the other hand, chemokines such as *IL-8* attract polymorphonuclear leukocytes from the blood to the infection site, which is reflected by an increase of somatic cell count (SSC) in milk [44]. The immediate recruitment of somatic cells from the blood into the udder is essential for effective elimination of intramammary pathogens [38]. *MCP-1* and *CXCL3* attract mononuclear leukocytes such as monocytes, natural killer cells, and activated lymphocytes [45]. It was demonstrated that *MCP-1* induces cell proliferation through activation of phosphatidylinositol 3 kinase (PI3K)/protein kinase B (PKB, also called AKT) and mitogen-activated protein kinase (MAPK) pathways, and prevents the LPS-induced inflammatory responses in bovine mammary epithelial cells (MAC-T cell line) [46]. Thus, immunobiotic *L. acidophilus* CRL2074 capable of reducing the magnitude of leukocyte migration into the udder, which is reflected in the expression of *IL-1 α* , *IL-8*, *MCP-1*, and *CXCL3*, might influence the clinical course of mastitis.

In the present study, *L. acidophilus* CRL2074 pre-stimulated BME cells showed significant upregulation of A20, SIGIRR, and Tollip expression after LPS challenge. The ubiquitin-editing enzyme A20 is recognized as a key regulator of TLR4 signaling, particularly involved in the negative feedback regulation of NF- κ B activation in the intestinal epithelial cells [47,48]. To the best of our knowledge, the effect of A20 and SIGIRR in the regulation of inflammatory responses in bovine mammary epithelium has not been reported before. Thus, our results would indicate for the first time the role of A20 and SIGIRR in the control of bovine mammary gland TLR4-triggered inflammation. On the other hand, Tollip has been implicated in the negative regulation of LPS-induced TLR4 signaling through the modulation of proinflammatory cytokines in bovine mammary epithelial cells [49]. Thus, the ability of the CRL2074 strain to differentially modulate the expression of three negative regulators when compared with the CRL2084 strain that regulated only a single factor would explain the higher ability of *L. acidophilus* CRL2074 to diminish proinflammatory factors expressions in the bovine mammary gland (Figure 6).

In conclusion, our results demonstrated that the *L. acidophilus* CRL2074 strain possesses remarkable immunomodulatory abilities against LPS-induced inflammation in BME cells. This *Lactobacillus* strain could be used as candidate for in vivo testing their beneficial effects in bovine mastitis through intramammary infusion. Our findings also suggest that the BME cells immunoassay system could be of value for the in vitro evaluation of the immunomodulatory abilities of LAB against the inflammation resulted from the intramammary infection with mastitis-related pathogens.

4. Materials and Methods

4.1. Cell Line and Culture Condition

The BME cell line used in this work was originally established by our group [25]. BME cells were derived from the mammary tissue taken from a 200 day pregnant Holstein Frisian cow. BME cells were maintained in Dulbecco's modified Eagle's medium (DMEM; Gibco Paisley, Scotland, United Kingdom) supplemented with 20% fetal calf serum (FCS; Sigma-Aldrich, Tokyo, Japan), 100 U/mL penicillin and 100 μ g/mL streptomycin (Gibco 15140122, Life Science Technologies), transferrin (5 mg/mL), and sodium acetate (5mM) as growth medium. For the passage, the BME cells were plated at the concentration of 2.5×10^5 cells/cm² in the 6-well cell culture plates (BD Falcon, Tokyo, Japan) and incubated in a humidified atmosphere of 5% CO₂. The cell culture medium was changed every 24 h. The cells used in this study belong to 22th to 28th passages.

4.2. Growth and Maintenance of Microorganisms

Four lactobacillus strains used in this study were obtained from CERELA-CONICET (Tucuman, Argentina). The LAB strains (Table 1) were originally isolated from the feedlot cattle's environment [26].

Table 1. Lactic acid bacteria used in this study.

Species	Strain ID	Source of Origin
<i>Lactobacillus mucosae</i>	CRL2069	cattle feces/pen soil/feed rations
<i>Lactobacillus acidophilus</i>	CRL2074	cattle feces/pen soil/feed rations
<i>Lactobacillus rhamnosus</i>	CRL2084	cattle feed rations
<i>Lactobacillus fermentum</i>	CRL2085	cattle feed rations

LAB strains were grown in Man, Rogosa, and Sharpe broth (MRS, Britania) at 37 °C for 18 h, and kept in milk yeast extract (10 g low fat milk, 0.5 h yeast extract, and 1 g glucose per 100 mL) with 12% glycerol at −20 °C. Before performing the experimental assays, bacteria were subcultured three times every 12–14 h at 37 °C in MRS broth. For preparing the bacterial inoculum, a culture of the strain (10^9 CFU) after incubation for 48 h at 37 °C in MRS broth was centrifuged, and the bacterial pellete was washed twice with saline solution (0.8% NaCl). Cells were suspended in 5 mL of DMEM (10% FCS, 1% SP) and counted under a microscope using a Petroff–Hausser counting chamber. The cell suspension was adjusted to a concentration of 10^9 CFU/mL followed by serial dilution in saline solution to have a concentration of 10^6 CFU/mL. This inoculum was fractionated and stored at 4 °C until the experiment was performed within a period no longer than 2 h [50].

4.3. Immunobiotic Evaluation Assay in BME Cells

In a first set of experiments, BME cells (5×10^5 cells per well) were plated in a 12-well cell culture plate and stimulated with LPS (1.0 µg/mL) or Pam3CSK4 (200 ng/mL). The cultures were maintained at 37 °C in a humidified atmosphere of 5% CO₂ for 3, 6, 12, or 24 h, and then the treated cells were harvested along with untreated control cells for measuring the mRNA expression of TLRs.

In second set of experiments, BME cells were seeded on a 24-well plate at 1.25×10^5 cells per well (500 µL) and cultured for 2 days at 37 °C in CO₂. When reached monolayer confluence on the third day of culture (2.5×10^5 cells per well), suspension of *L. mucosae* CRL2069, *L. acidophilus* CRL2074, *L. rhamnosus* CRL2084, or *L. fermentum* CRL2085 (5.0×10^7 cells per well) or Pam3CSK4 (200 ng/mL) were added to the BME cultures. The LAB strains were subjected to heat treatment at 72 °C for 90 min prior to stimulation. The bacterial stimulation of BME cell culture was performed for 12, 24, or 48 h at 37 °C in 5% CO₂. At each time point, LPS (1.0 µg/mL) was added after washing the cells twice with PBS. BME cells were further cultured for 3, 6, or 12 h at 37 °C in 5% CO₂ and cells were harvested for RNA isolation at each time point.

4.4. Real-Time Quantitative PCR

Two-step real-time PCR (RT-qPCR) was performed for quantification of selected mRNAs in BME cells. Total RNA was extracted from the treated and untreated BME cells using PureLink RNA Mini kit (Life Technologies Inc., Carlsbad, USA) along with on-column DNase treatment. The primer sequences used are presented in Table 2. The cDNA synthesis was performed using the quantiTect reverse transcription kit (Qiagen, Tokyo, Japan) according to the manufacturer's recommendations. RT-qPCR was performed using a 7300 real time PCR system (Applied Biosystem, Warrington, United Kingdom) using the TaqMan gene expression assay kit (Life Technologies Inc., Carlsbad, USA) and TaqMan Universal Master Mix II with UNG (Applied Biosystem, Warrington, United Kingdom). The PCR thermal cycling conditions were 2 min at 50 °C, followed by 10 min at 95 °C, and then 40 cycles of 15 s at 95 °C, 1 min at 60 °C. The reaction mixtures contained 2.5 µL of cDNA, 1 µL of gene expression assay, 10 µL of TaqMan Universal Mix II with UNG, and 6.5 µL distilled water. According to the minimum

information for publication of RT-qPCR experiments guidelines, β -actin was used as a housekeeping gene because of its high stability across various bovine tissue [51]. Relative index was calculated as the ratio of target gene expression of β -actin. Then, raw data were transformed from the mean CT values of replicated samples to copy number of the established standard curve.

4.5. Statistical Analysis

The raw data were \log_2 transformed followed by a normality check using the Kolmogorov–Smirnov test. Comparisons between mean values were carried out using one-way ANOVA and Fisher's least significant different test. For every case, $p < 0.05$ was considered statistically significant.

5. Conclusions

Taking into consideration that the appropriate regulation of the production of proinflammatory mediators is highly important to maintain immune homeostasis and to prevent excessive inflammatory injury to the mammary gland, *L. acidophilus* CRL2074 may have the potential to be used as an immunobiotic strain to prevent and to treat bovine intramammary infections. This *Lactobacillus* strain could be used as a candidate for in vivo testing of beneficial effects in bovine mastitis through intramammary infusion. Our findings also suggest that the BME cells immunoassay system could be a useful tool for the evaluation of the immunomodulatory abilities of LAB against the inflammation resulting from the intramammary infection with mastitis-related pathogens.
