# Records and Stratigraphical Ranges of South American Tayassuidae (Mammalia, Artiodactyla)

Germán Mariano Gasparini

Published online: 24 September 2011  
 © Springer Science+Business Media, LLC 2011

**Abstract** Tayassuidae represent one of the first mammalian immigrants that entered South America during the “Great American Biotic Interchange.” However, the exact moment of its arrival for the first time in South America is controversial. Three genera are recognized in South America: *Platygonus*, *Catagonus*, and *Tayassu*. This paper aims to: (1) review the paleontological record of the South American Tayassuidae and update it; and (2) discuss its geographical and stratigraphical distribution pattern in South America. The genus *Platygonus* (middle Pliocene to early Pleistocene) is registered in Argentina, Uruguay, Colombia, and Bolivia; *Catagonus* (late Pliocene? to Recent) in Argentina, Uruguay, Brazil, and Bolivia; and *Tayassu* (middle Pleistocene to Recent) in Argentina, Uruguay, and Brazil. *Platygonus* and *Catagonus* have adaptations to dry and relatively open environments; in contrast, *Tayassu* is adapted mainly to humid climates and woodland and forest environments. The faunal changes that took place since the middle-late Pliocene could have been strongly influenced by climate. Open and arid environments developed during the glacial cycles, allowing the latitudinal expansion of *Platygonus* and *Catagonus*. Considering ecological and anatomical information, it is possible to infer that *Platygonus* species were replaced by those of *Catagonus* since the middle Pleistocene, probably due to a reduction of the open environments to which *Platygonus* species were better adapted. The alternation of these mainly arid or semiarid,

cold conditions with warmer and more humid short pulses would have allowed the posterior expansion of *Tayassu* species. According to phylogenetic analysis and chronological as well as geographical evidence, *Platygonus* and *Catagonus* represent two Tayassuidae lineages that originated in North America and then migrated to South America. This migration would have occurred on more than one occasion and with different taxa. Evidence indicates that *Tayassu* represents a lineage that differentiated in the Southern Hemisphere and then migrated to North America.

## Introduction

The family Tayassuidae (Mammalia, Artiodactyla) entered North America from Eurasia (Wright 1998; Hulbert 2001; Prothero 2009) and, then extended its range into South America during the “Great American Biotic Interchange” (GABI). However, the exact moment of its arrival for the first time in South America is controversial. Several authors (Reig 1952; Kraglievich 1959; Prevosti et al. 2006; Woodburne 2010) cite tayassuids for the first time in the middle Pliocene (ca. 4–3.3 Ma) in sediments outcropping on the southeastern coast of Buenos Aires Province, Argentina. In contrast, Campbell (2010) and Campbell et al. (2010) mention two indeterminate forms of extinct peccaries, among other mammals of Nearctic origin (e.g., gomphotheres, tapirs), coming from the basal levels (9.5 Ma.) of Madre de Dios Formation outcrops in southeastern Peru (Madre de Dios Department). Another possible Tertiary tayassuid record

comes from Colombia, but the chronological information about the bearing sediments of those remains is not accurate (Stirton 1947).

The Tayassuidae (commonly known as peccaries or javelinas) had a great taxonomic diversity and a wide geographic distribution in the past. There are records of tayassuids [i.e., *Tayassuinae* sensu McKenna and Bell (1997)] in Asia (late Eocene); North America (late Eocene to Holocene); Central America (late Miocene to Holocene); and South America (middle Pliocene to Holocene) based on the studies of McKenna and Bell (1997), Gasparini (2007), and works cited therein. The greatest generic and specific diversity of Tayassuidae in South America derives from sediments exposed in Argentina. The family has also been found in Brazil, Uruguay, Bolivia, Colombia, and Peru (Rusconi 1930; Stirton 1947; Rusconi 1952; Paula Couto 1975, 1981; Rancy 1999; Ubilla 2004; Ubilla et al. 2004; Gasparini 2007; Gasparini et al. 2009a, b, 2010b; Campbell 2010; Campbell et al. 2010). However, in the modern fauna, tayassuids have a lower generic and specific diversity, and they are distributed in the American continents from the southwestern USA to north-central Argentina (Mayer and Brandt 1982; Redford and Eisenberg 1992; Gasparini et al. 2005, 2006).

This paper aims to: (1) review the paleontological record of the South American Tayassuidae and update it; and (2) discuss its geographical and stratigraphical distribution pattern in South America.

## Systematics of South American Tayassuidae

According to Gasparini (2007), three genera of Tayassuidae are recognized in South America: *Platygonus* Le Conte, 1848, with five extinct species; *Catagonus* Ameghino, 1904, with five species, one of them actually extant; and *Tayassu* Fischer, 1814, with two extant species.

The following species of tayassuids are recognized in South America:

Genus *Platygonus* Le Conte, 1848: *Platygonus kraglievichi* Rusconi, 1930; *Platygonus scagliai* Reig, 1952; *Platygonus marplatensis* Reig, 1952; *Platygonus chapadmalensis* (Ameghino, 1908); and *Platygonus cinctus* (Ameghino, 1886).

Genus *Catagonus* Ameghino, 1904: *Catagonus metropolitanus* Ameghino, 1904; *Catagonus bonaerensis* (Ameghino, 1904); *Catagonus carlesi* (Rusconi, 1930); *Catagonus stenocephalus* (Lund in Reinhardt, 1880); and *Catagonus wagneri* (Rusconi, 1930).

Genus *Tayassu* G. Fischer de Waldheim, 1814: *Tayassu pecari* (Link, 1795); and *Tayassu tajacu* (Linnaeus, 1758).

## Materials and Methods

This paper adopts the classificatory system proposed by Gasparini (2007), because this is the most current integrative review of the South American Tayassuidae.

The materials studied are in Tables 1 and 2. The geographical location of the paleontological and archaeological sites mentioned in this contribution, are showed in Fig. 1.

## Results and Discussion

### Distributional and Stratigraphical Ranges of Tayassuidae in South America

Although peccaries represent one of the first North American mammalian immigrants that migrated to South America during the “Great American Biotic Interchange” (Prevosti et al. 2006; Woodburne et al. 2006; Gasparini 2010; Woodburne 2010), its oldest fossil record in South America is controversial. Fossil remains of tayassuids of

to Tayassinae indet. (MMP-S 751) (Prevosti et al. 2006) and to *P. marplatensis* (MMP-S 25 type; MACN 5420, MMP-S 200, MMP-S 188, MMP-S 199, MMP-S 674). These remains come from the Chapadmalal “Formation” exposed in Barranca de Los Lobos (General Pueyrredón county, Buenos Aires Province, Argentina; see Kraglievich 1952). The species *P. chapadmalensis* (MACN 6637 type) from the Chapadmalal region (General Pueyrredón county, Buenos Aires Province, Argentina) possibly represents

another one of the oldest records of South American tayassuids, but the chronological information for the bearing sediments is not accurate (middle Pliocene?; see Ameghino 1908; Kraglievich 1952).

**Fossils Records During the Late Pliocene** The greatest specific diversity of *Platygonus* is recognized during this time period in South America; they are registered mainly in Argentina, Uruguay, and possibly in Colombia.

In Argentina, *P. marplatensis* (MACN 19725, MACN 19726), *P. chapadmalensis* (MMP-S 246), *P. scagliai* (MMP-S 156 type, MMP-M 878, MMP-S 553) and *Platygonus* sp. (MMP 1139, MMP-S 556, MLP 92-IV-1-1, MMP 1212, MMP-M 1617) are registered in Buenos Aires Province. The species *P. scagliai* and certainly *P. chapadmalensis* are registered for the first time in South America. These three species come from the coastal cliff in the Chapadmalal region (General Pueyrredón and General Alvarado counties), in the southeastern Buenos Aires Province (Ameghino 1908; Reig 1952; Gasparini 2004, 2007). In Jujuy Province, fossil remains of peccaries have been exhumed from late Pliocene sediments of two localities. The species *P. kraglievichi* (MACN 5341 type) and *Platygonus* sp. (MACN 5337, MACN 5338, MACN 5339, MACN 5340) are registered in Uquia locality; and *Platygonus* sp. (MLP 86-V-10-14) is recorded in Esquina Blanca locality (Rusconi 1930; Gasparini 2007; Reguero et al. 2007; Reguero and Candela 2008).

Coming from sediments possibly referred to Barranca de Los Lobos Formation (lower part of the formation; late Pliocene?), exposed in southern Buenos Aires Province, a skull (MMP 972) identified as *Catagonus* sp. was found. This specimen could be the oldest record of the genus in South America; however, its stratigraphic provenance is uncertain.

In Uruguay (Canelones Department), *Platygonus* sp. (FC-DPV-444) is registered in the Raigón? Formation (Pliocene- early Pleistocene; see Gasparini and Ubilla 2009). This finding represents the only record of the genus in Uruguay, and the oldest one of the family in Uruguayan territory.

In Colombia (Cocha Verde, Nariño locality), *Platygonus* sp. (unknown number MSGC) is registered with uncertain stratigraphic provenance. This record is considered doubtful, because the only available information indicates that it comes from sediments tentatively assigned to late Pliocene without any specific data (see Stirton 1947). In turn, Menézaz and Ortiz Jaureguizar (1995), considering the hypotheses of Kraglievich (1959: 233–234) and Reig (1981: 41), suggest a lower to middle Pliocene age for those bearing sediments.

**Fossils Records During the Early To Middle Pleistocene** During this period of time, the findings of *Platygonus* fossils in

South America markedly decrease and, *Catagonus* is recorded unquestionably for the first and only time in Argentina.

The genus *Platygonus* is recorded only in Buenos Aires Province, Argentina and in the Tarija valley, Bolivia. It is precisely in this period of time when the only known *Platygonus* species [*P. cinctus*, unknown number MACN type (missing)] is recorded in the “toscas del río de La Plata,” in the environs of Buenos Aires city (see Soibelzon et al. 2008). This represents the youngest reliable record of the genus *Platygonus* in South America.

Fossil remains determined as *Platygonus* sp. have been found in the coastal cliffs in Miramar city (MACN 10959, General Alvarado county, Buenos Aires Province, Argentina; see Rusconi 1930; Gasparini 2007) and in the Tarija valley (MACN 525, Bolivia; see Gasparini et al. 2010b). However, the age of the bearing sediments of both records is uncertain (early to middle Pleistocene?) as is their stratigraphic provenances.

During this period of time, the genus *Catagonus* is recorded in Argentina; precisely, *C. metropolitanus* (MACN 850 a and b type) and *Catagonus* sp. (unknown number Henning collection, MACN 5239, MACN 5242, MACN 8849) are registered in the “toscas del río de La Plata” (the environs of Buenos Aires city) (Soibelzon et al. 2008). In turn, *C. stenocephalus* (MMP 41) and Tayassuinae indet. (MLP 268, MACN 10896) are recorded in the coastal cliffs in the southeast of Buenos Aires Province.

**Fossils Records During the Middle Pleistocene to Earliest Holocene** The greatest specific diversity and abundance of *Catagonus* is documented during this time in South America (e.g., Argentina, Brazil, Uruguay, and Bolivia); in the middle Pleistocene, the genus *Tayassu* appears for the first time in the South American fossil record.

In Argentina, *C. stenocephalus* [MCA 2001 (see Gasparini 2004), MACN 7000, MACN 10083], *C. bonaerensis* (MACN 2440 type), *Catagonus* sp. (MMP-S 707), *T. tajacu* (MMH 186, MACN 6182, MLP 52-X-3-62), *T. pecari* (MACN 10512, MACN 6427, MACN 10465, MACN 7114), *Tayassu* sp. (MACN 6183, MLP 52-XI-5-2, MLP 60-VI-16-1, MACN 7003), and Tayassuinae indet. (MLP, 64-VI-9-1, MLP 64-VI-9-8, MLP 92-XI-28-5, MLP 92-XI-28-1) have been recorded in several localities in the northern, eastern, and southeastern Buenos Aires Province. In the Mesopotamian region, *Catagonus* sp. (CICYTTP-PV-M-1-107, CICYTTP-PV-M-1-108) is known from sediments of the “Feliciano Stream Formation” (late Pleistocene) outcropping in Entre Ríos Province (Gasparini and Ferrero 2010); *T. pecari* (Ctes-PZ UNNE 1599, Ctes-PZ UNNE 1603, Ctes-PZ UNNE 3562) is documented from sediments of the Yupoí Formation (late Pleistocene) in Corrientes Province (Gasparini and Zurita 2005); and

*Tayassu* sp. (MLP 52-X-2-53) is recorded in Entre Ríos Province (Gasparini and Ferrero 2010). In the central region of Argentina, *C. carlesi* (MACN 1308 type) is registered in Santiago del Estero Province (middle Pleistocene? sic Rusconi 1930); *T. pecari* (MFA-PV 1172) is known from sediments of the Tezanos Pinto Formation (late Pleistocene to earliest Holocene) outcropping in Santa Fe Province (Gasparini et al. 2011); and *Tayassu* (MACN 5234) sp. in Córdoba Province.

In Uruguay, four species of Tayassuidae are recorded. Specifically, in the Sopas Formation [ $>45,000$  RCYBP;  $43,500 \pm 3600$  and  $58,300 \pm 7400$  CALYBP (TL dates); see Ubilla 2004] that outcrops in the central and northern region, the species *C. wagneri* (MHD-P-9) (Artigas Department), *C. stenocephalus* (MACN-S-10) and *Tayassu pecari* (FC-DPV-1057) (Salto Department) are registered (Gasparini et al. 2009a, b, 2010a, b; Gasparini and Ubilla 2010). In turn, in the southern region, the species *Tayassu* sp. (CPR 557) (Libertad Formation?, middle-late Pleistocene, Soriano Department; see Roselli 1976; Gasparini 2007), *C. bonaerensis* (MDC 1345), and *Catagonus* sp. (MDC 398) (middle Pleistocene?, Colonia Department; see Rusconi 1952; Gasparini 2007) are recorded.

In Brazil, *Catagonus* and *Tayassu* species are registered in the fossil record. Thus, during the late Pleistocene, *C. stenocephalus* is registered in Lagoa Santa (ZMK 8638 and 8617 type; Minas Gerais State; see Fonseca 1979; Paula Couto 1975, 1981); in sediments of Touro Passo Formation outcropping in the Touro Passo Stream (MCPU-PV 029; Uruguaiana, Rio Grande do Sul State; see Gasparini et al. 2009a, b); and in Gruta dos Moura (Aurora de Tocantins, Tocantins State; see Avilla et al. 2010). In turn, *Catagonus* cf. *C. stenocephalus* is known from late Pleistocene sediments outcropping in Gruta do Vale do Ribeira (UFPR 0118 PV; Paraná State; see Dias da Silva et al. 2010). There are records of *T. pecari* in Lagoa Santa (late Pleistocene; Minas Gerais State) (Fonseca 1979); in Rio Grande do Sul, Mato Grosso do Sul (Paula Couto 1975); in Gruta do Vale do Ribeira (late Pleistocene; Paraná State; MCN.P.1124; see Dias da Silva et al. 2010); and in Piauí, Ceará and Amazonas states (Rancy 1999). The species *T. tajacu* is recorded in Lagoa Santa (late Pleistocene; Minas Gerais State; see Fonseca 1979); in Ceará State (Fonseca 1979); and in Gruta do Vale do Ribeira (late Pleistocene; Paraná State; MCN.P.1123; see Dias da Silva et al. 2010).

It is notable that in Bolivia, there are records of *C. stenocephalus* (MNPA-V 1450) in Tarija valley; and Tayassuinae indet (without reference material or repository) in Potosí Department and Ñuapua Formation (see Gasparini et al. 2010b). However, the ages of the bearing sediments of Bolivian records are wide (Pleistocene) and their stratigraphic provenances are unknown (see Gasparini et al. 2010b).

**Fossils Records During the Holocene** The diversity and the abundance of tayassuids records in South America markedly decrease during this period, registering in Argentina mainly, and Brazil.

In Argentina, records of *C. wagneri* (MACN 14670 type, MACN 14671, MACN 14672, MACN 14673) and *Tayassu* cf. *T. pecari* appear in archaeological sites from Santiago del Estero Province [Rusconi 1930; ca. 1000 RCYBP (see Tonni 2006)]. In Buenos Aires Province, *T. pecari* (unknown number MLP) is documented from the archaeological site “Islas Las Lechiguanas I”; the age of the level from which these remains were found is 2.740 ± 80 and 2.550 ± 90 years BP  $^{14}\text{C}$  (2.926–2.759 and 2.755–2475 years cal BP respectively; see Gasparini and Soibelzon 2003). In turn, *Tayassu* sp. (FCS.CLA.82) is recorded in the archaeological site “Campo Laborde”, located in the upper basin of Tapalqué Creek (ca. 9700 and 6700 years BP  $^{14}\text{C}$ ; see Politis and Messineo 2008). In the Argentine Mesopotamian, *T. pecari* is cited in the archaeological site Panambí (Department of Oberá, Misiones Province); the level of the remains was dated to 920 ± 70 years BP radiocarbon (LP-176), (732–925 years cal BP, 1.025–1.218 AD) (Tonni 2004).

In the Holocene of Brazil, a very few remains of tayassuids are registered. Recently, Parisi Dutra et al. (2010) mentioned some remains of *Tayassu* sp. (LDS-01, LDS-80) from the archaeological site Lapa do Dragão (Minas Gerais State). The level where those remains were found was dated to ca. 2100 years BP.

**Records in Recent Times** According to Gasparini (2007), Tayassuidae are represented by three extant species: *T. pecari*, *T. tajacu*, and *C. wagneri*. However, a new extant species of even-toed ungulate from the Brazilian Amazonia was recently reported (Van Roosmalen et al. 2007). The systematic position (generic and specific levels) of this “giant” peccary (sensu Van Roosmalen et al. 2007) is uncertain according to the systematics presented here.

The species *T. tajacu* has the largest geographic distribution, recorded from north-central Argentina to southwestern USA; *T. pecari* has a more restricted distribution, recorded from north-central Argentina to southern Mexico. Finally, *C. wagneri* is endemic to the Great Chaco of Argentina, Paraguay, and Bolivia (Mayer and Brandt 1982; Redford and Eisenberg 1992; Gasparini et al. 2006).

#### Ecological and Anatomical Considerations

The peccaries of *Platygonyus* and *Catagonus* were large-sized mammals with some morphological features (e.g., orbits located in posterodorsal position and behind the M3

due to elongation of the rostrum, great development of nasal sinuses and chambers, a distinct basicranial flexure, reduction of the lateral digits in the limbs) supporting the inference that these animals lived in dry and relatively open environments (Guilday et al. 1971; Wetzel 1977; Menézaz and Ortiz Jaureguizar 1995; Gasparini et al. 2010a, b). In contrast, *Tayassu* has certain morphological characters (e.g., orbits located anterior to the posterior border of the M3 due to shortening of the rostrum, poor development of nasal sinuses and chambers, a poor basicranial flexure, development of the lateral digits in the limbs) that indicate that they are adapted mainly to humid climates and woodland and forest environments. However, the presence of *Tayassu* is insufficient to infer environmental conditions, because of its extensive geographic range and ecological tolerances (Menézaz and Ortiz Jaureguizar 1995; Gasparini and Zurita 2005; Gasparini 2007). In turn, preliminary studies have shown that in the last 3.3 Ma, the South American Tayassuidae have maintained a relatively uniform body mass, ranging between 20 and 70 kg, with some exceptions [e.g., *C. bonaerensis* and *C. metropolitanus*; (see Gasparini et al. 2010a)].

#### Conclusions

The family Tayassuidae is recorded in South America from middle Pliocene to Recent times. However, if the systematic assignation of the remains coming from the Madre de Dios Formation outcropping in southeastern Peru is verified, the first arrival in South America would be older (late Miocene).

There are fossils records of *Platygonyus* (middle Pliocene to early Pleistocene) in Argentina, Uruguay, Bolivia, and Colombia; *Catagonus* (late Pliocene?, early Pleistocene to Holocene) in Argentina, Uruguay, Brazil, and Bolivia; and *Tayassu* (middle Pleistocene to Holocene) in Argentina, Uruguay, and Brazil.

On the basis of what was exposed before, Argentina has the greatest diversity and abundance of South American tayassuids species. Brazil and Uruguay have an interesting diversity and a great abundance of fossil records. In turn, in the Pampean region (mainly in Buenos Aires Province, Argentina) and in southern Uruguay, the three South American genera of peccaries are registered.

The *Platygonyus* species recognized in South America are: *P. marplatensis* [middle to late Pliocene; Argentina (Buenos Aires Province)]; *P. chapadmalensis* [middle? to late Pliocene; Argentina (Buenos Aires Province)]; *P. kraglievichi* [late Pliocene; Argentina (Jujuy Province)]; *P. scagliai* [late Pliocene; Argentina (Buenos Aires Province)]; and *P. cinctus* [early to middle Pleistocene; Argentina (Buenos Aires Province)].

The *Catagonus* species recognized in the South American fossil record are: *C. metropolitanus* [early to middle Pleistocene; Argentina (Buenos Aires Province)]; *C. bonaerensis* [late Pleistocene to earliest Holocene; Argentina (Buenos Aires Province) and Uruguay (Colonia Department)]; *C. carlesi* [middle Pleistocene?; Argentina (Santiago del Estero Province)]; *C. stenocephalus* [early Pleistocene to earliest Holocene; Argentina (Buenos Aires Province), Brazil (Minas Gerais, Rio Grande do Sul, Tocantins and possibly Paraná states), Bolivia (Tarija valley), and Uruguay (Salto Department)]; and *C. wagneri* [late Pleistocene to Holocene; Argentina (Santiago del Estero Province) and Uruguay (Artigas Department)].

The *Tayassu* species distinguished in the South American fossil record are: *T. tajacu* [middle Pleistocene to earliest Holocene; Argentina (Buenos Aires Province) and Brazil (Minas Gerais, Ceará and Paraná states)]; and *T. pecari* [middle Pleistocene to Holocene; Argentina (Buenos Aires, Santa Fe, Corrientes, Misiones and possibly Santiago del Estero provinces), Brazil (Minas Gerais, Rio Grande do Sul, Mato Grosso do Sul, Piauí, Ceará, Amazonas and Paraná states), and Uruguay (Salto Department)].

During the end of the Tertiary (middle-late Pliocene), *Platygonus* is the only tayassuid that undoubtedly was present in South America. However, if the age of the bearing sediments of the specimen 972 MMP is verified (lower part of the Barranca de Los Lobos formation, late Pliocene?), this would correspond to the oldest record of *Catagonus* in South America. This could indicate the possible coexistence of *Catagonus* and *Platygonus* during this time interval in Buenos Aires Province, Argentina.

During the Quaternary (Pleistocene and Holocene), evidence of possible coexistence has been registered in South America. The fossil record of tayassuids suggests a possible coexistence of *Catagonus* and *Platygonus* during the early to middle Pleistocene in the Pampean Region (mainly in Buenos Aires Province, Argentina), similar to that recorded during the Pleistocene in Bolivia (Tarija valley). In turn, the paleontological information raises the possible coexistence of *Catagonus* and *Tayassu* during the middle Pleistocene to earliest Holocene in the Pampean Region (mainly in Buenos Aires Province, Argentina), similar to that registered during the late Pleistocene in the Argentine Mesopotamian, in Minas Gerais (Brazil), and in northern Uruguay. The last relationship mentioned can also be observed during the Holocene in Santiago del Estero Province (Argentina), and actually in the Great Chaco.

The faunal changes that took place since the middle-late Pliocene could have been strongly influenced by climate. Open and arid environments developed during the glacial cycles, allowing the latitudinal expansion of *Platygonus* and *Catagonus*. Certain shared anatomical features linked to the type of diet and habit, together with body mass, make

it possible to infer that *Platygonus* species were replaced by those of *Catagonus* since the middle Pleistocene, probably due to a reduction of the open environments to which *Platygonus* species were better adapted. In turn, the alternation of these mainly arid or semiarid and cold conditions with warmer and more humid short pulses would have allowed the posterior expansion of *Tayassu* species.

According to phylogenetic analysis and chronological as well as geographical evidence, *Platygonus* and *Catagonus* represent two Tayassuidae lineages that originated in North America and then migrated to South America. This migration would have occurred on more than one occasion and with different taxa. Evidence indicates that *Tayassu* represents a lineage which differentiated in the Southern Hemisphere and then migrated to North America.

**Acknowledgements** The author thanks to Cecilia Morgan for improving the English version; to Alfredo A. Carlini and Diego Brandoni for reading and commenting on an early version of the manuscript; to the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) for permanent financial support; and to the authorities of paleontological collections for providing material for analysis. Two anonymous reviewers and associated editor provided significant suggestions to improve the ms.
