The GINI project investigates the dynamics of inequality among populations over the long term by synthesising global archaeological housing data. This project brings archaeologists together from around the world to assess hypotheses concerning the causes and consequences of inequality that are of relevance to contemporary societies globally.

Keywords: socioeconomic inequality, income, Gini coefficient, households, distributions of housing

Received: 21 May 2023; Revised: 8 September 2023; Accepted: 20 October 2023

Introduction

Growing economic disparity around the world has prompted a renewed interest in the long-term dynamics of inequality (Borgerhoff Mulder *et al.* 2009; Flannery & Marcus 2012; Piketty 2014). Archaeology is uniquely placed to investigate these dynamics by offering data and expertise in what constitutes wealth and how institutional mechanisms have shaped inequality over the long term (Chirikure *et al.* 2018). There is much to learn from our accumulated data. A previous collaboration (Kohler *et al.* 2017) revealed surprising continental-scale differences.

GINI (The **G**lobal Dynamics of **I**Nequal**I**ty Project) brings together archaeologists working across the globe (Figure 1A). Our aim is to investigate the causes and consequences of socioeconomic inequality over prolonged periods across various world regions using metrics of contemporary relevance.

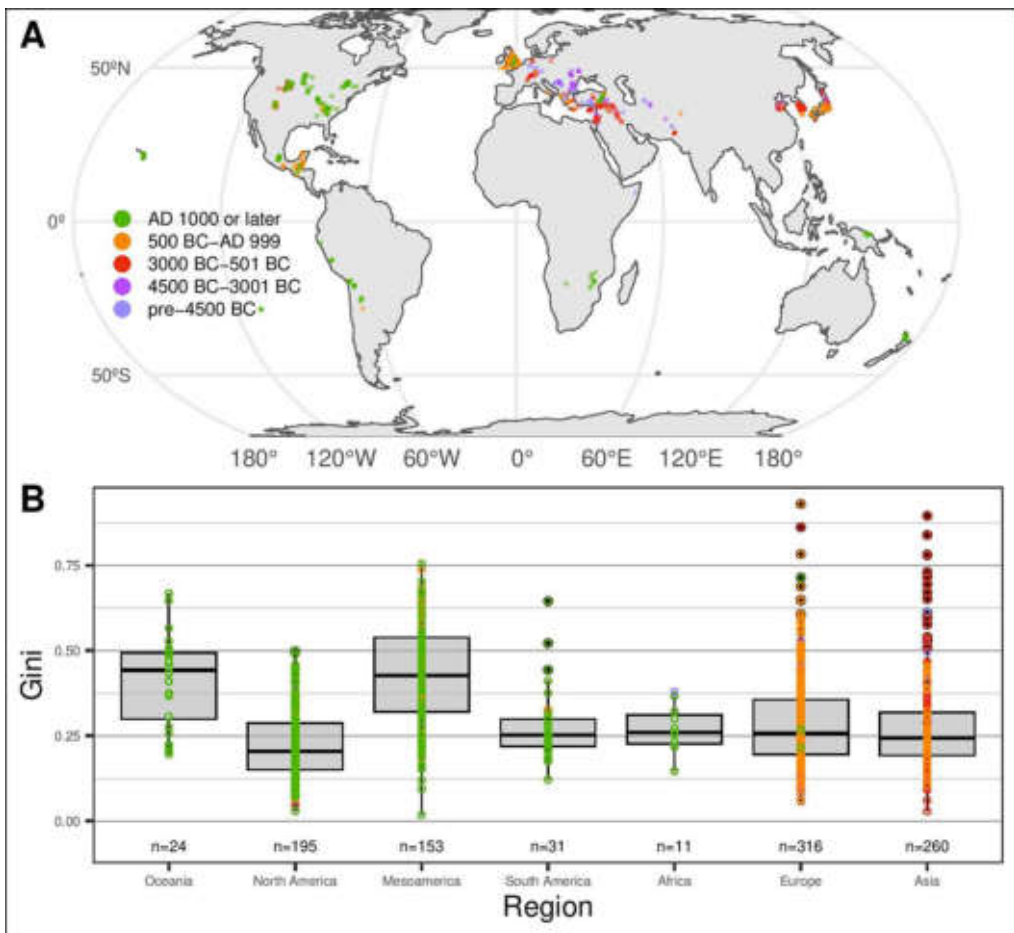

Figure 1. Locations and mean site dates for sites in the GINI Project database as of 16/11/2023. A) all sites; B) boxplots of Gini's for sites with five or more houses by major world region and mean site date (see legend A). Gini's are computed by site on the total area per house, including storage (figure by Tim Kohler).

Project background

It has been argued that human societies have a persistent attraction to inequality (Scheffer *et al.* 2017; Chase *et al.* 2020), reflected in the skewed degree distributions of network science, where a few nodes have more links than the rest (Bettencourt 2021). Mobile foragers have often been characterised as classless, but some hunter-gatherer-fishers developed marked wealth inequalities, including on a seasonal basis (Wengrow & Graeber 2015; Mattison *et al.* 2016; Pandit *et al.* 2020). Wealth inequalities can intensify with the implementation of agriculture, a process apparently amplified by domesticated animals (Kohler *et al.* 2017; Styring *et al.* 2017). Within a few millennia of agricultural emergence, some societies exhibited enormous wealth and power differences, while others apparently suppressed high inequality and have attracted particular scrutiny by archaeologists (e.g. McIntosh 2005; Graeber & Wengrow 2021; Green 2021). Preserved housing evidence, such as the stone house foundations of Hawai'i Island (Figure 2) and houses and granaries in the Intersalar region, Bolivia (Figure 3), provide key data on past wealth distributions among households.

Figure 2. Aerial view of stone foundations of houses along the coast of Hawai'i Island, Lapakahi State Historical Park (photograph by Mark D. McCoy).

Figure 3. Aerial view of the Loma Pucara site of Ayque (Intersalar Region, Potosi, Bolivia), an altiplanic settlement of the Late Intermediate Period, around AD 1300 (photograph by Pablo Cruz).

Aims of the project

GINI examines Holocene distributions of housing area (i.e. house floor area or size), a continuous variable that has been recorded across archaeological and contemporary datasets. As a proxy for inequality, housing has clear limitations: it constrains our focus to comparisons among residential units and its relationship to inequality may be confounded by other variables. We measure inequality by calculating Gini coefficients over house area distributions and storage capacities within sites and at larger scales of aggregation. We also assess potential biases in sampling, multiproxy indicators of wealth and measures of uncertainty (Fochesato *et al.* 2019; Fochesato & Bowles 2022; Munson & Scholnick 2022).

The project aims to consider global questions and hypotheses about wealth production, distribution and governance. How is resistance to high wealth inequalities achieved (Kohler & Higgins 2016; Hodder 2022)? Do societies develop sustained high or low levels of inequality under particular forms of governance (Blanton & Fargher 2008)? What is the role of labour- versus land-limited production (Bogaard *et al.* 2019)? How do the spatial distribution and visibility of housing disparities across settlement systems relate to the persistence of high or low inequality? Addressing such questions requires synthesis of diverse records of housing, ranging from Great Zimbabwe in southern Africa (Figure 4) to Neolithic Mehrgarh in the Indus River basin (Figure 5).

Figure 4. The Great Enclosure (c. AD 1250–1450) at Great Zimbabwe. The drystone walls enclosed courtyards where multiple houses were built (photograph by Shadreck Chirikure).

Figure 5. Neolithic mudbrick houses at Mehrgarh, Indus River basin, Pakistan (photograph by Catherine Jarrige © Mission Archéologique de l'Indus).

We also investigate how house-size distributions reflect wealth inequality today. Large housing datasets and associated economic information (e.g. Leyk *et al.* 2020) enable assessment of what house sizes represent in contemporary contexts. We assess how far our findings reflect processes common to the past and present.

So far, we have assembled archaeological data on approximately 45 000 houses, ranging in date from more than 20 000 years ago in Western Asia to twentieth-century Melanesia. Preliminary results (Figure 1) show high variability in Gini coefficients, especially in Asia, Europe and Mesoamerica, where data are most abundant. Ongoing analyses seek to disentangle temporal, spatial and ecological trends within and across world regions, including those under-represented in previous work.

GINI pushes beyond categories such as ‘hierarchical’ and ‘egalitarian’ to examine the tensions between these polar modes of social organisation and how inequities are negotiated in particular times and places. If persistent levels of low inequality require fundamental social and economic commitments (e.g. Osborne 2007; Hodder 2022), monitoring long-term archaeological records deserves our closest attention.

Acknowledgements

We thank the Santa Fe Institute for hosting workshop activity for this project. We also thank Dr Aurore Didier for kindly providing access to the photograph of Mehrgarh.

Funding statement

The GINI project is funded by the National Science Foundation (NSF grant no. BCS-2122123) and supported by the Coalition for Archaeological Synthesis (CfAS, <http://www.archsynth.org/>) and the Center for Collaborative Synthesis in Archaeology (CCSA, <https://ibsweb.colorado.edu/archaeology/>).
