16

17 **Running title:** Patterns of acoustic phenology in anurans of the Yungas

18

19 **Abstract.** Breeding seasons in anurans are usually noticed by their advertisement calls,
20 which stand as the main signal emitted by males during their adult life. These calls are
21 species-specific signals with multiple information and can be used to monitor anuran
22 populations over extended time periods. Applying a Passive Acoustic Monitoring method
23 (PAM), we described the acoustic breeding phenology of an anuran assemblage along an
24 altitudinal elevation range in the Yungas Andean Forest of Argentina. In addition, we
25 propose a new classification system for their acoustic phenological strategies, based on

26 the male's calling records throughout an entire year. Also, we assessed the temporal and
27 spectral niche overlap by the anuran species recorded. The assemblage was active
28 throughout the entire year, with a higher concentration of calls recorded during the spring-
29 summer season. We describe five distinct Acoustic Breeding Strategies based on the
30 calling patterns of the recorded species. Temporal niche overlap was higher in the spring-
31 summer season and in the lowest study site. The use of a PAM as a tool to monitor the
32 advertisement calls in anurans communities could be a reliable technique to obtain
33 different information about the species' acoustic phenology and the temporal use of the
34 acoustic communication channel.

35
36 **Keywords.** Acoustic breeding strategies, acoustic phenology, advertisement calls,

38 39 INTRODUCTION

40
41 Advertisement calls are the main signals emitted by anurans during the breeding season
42 (Wells, 2007). These species-specific features are mainly expressed by males, with some
43 exceptions in females (e. g., the bullfrog *Lithobates catesbeianus*) of certain species, and
44 voiceless males like *Rhinella gallardoi* (Emerson and Boyd, 1999; Carrizo, 1992).
45 Advertisement calls are considered key factors for mate selection (Márquez and Verrell,
46 1991; Gerhardt and Huber, 2002; Wells and Schwartz, 2007) and are used by receivers
47 according to their temporal and spectral characteristics, both for identification and
48 location of their potential pairs, as well as to recognize the quality of the emitter (Gerhardt
49 and Schwartz, 2001; Mason, 2007). Thus, these signals are used in mate choice behaviour,
50 transmitting several messages simultaneously (Candolin, 2003). In addition, due to their

51 “species-specific” nature, these are used as a taxonomic character for species description
52 and identification (Köhler *et al.*, 2017). Thus, advertisement calls have been widely used
53 in long-term monitoring programs (Bridges and Dorcas, 2000; Dorcas *et al.*, 2009; Llusia,
54 2013; Márquez *et al.*, 2014; Measey *et al.*, 2016). The surveying of advertisement calls
55 has proven to be a useful technique for detection and monitoring of anuran species at
56 large spatial scales (de Solla *et al.*, 2006), as well as for assessing population changes
57 over time (Buckley and Beebee, 2004; Pieterse *et al.*, 2006). These kinds of surveys can
58 also provide valuable information about threatened species that breed in narrow time
59 windows or display sporadic calling activity (Williams *et al.*, 2013; Willacy *et al.*, 2015;
60 Akmentins and Boullhesen, 2020).

61 The breeding phenology of anurans, monitored through their advertisement calls,
62 can be explored at different time scales, mainly in regions where seasonality shapes the
63 extent, the start, and ending of their breeding activity (Weir and Mossman, 2005).
64 Thereby, different species may have distinct daily and seasonal calling patterns (Cook *et*
65 *al.*, 2011; Yoo *et al.*, 2012). Studying these calling patterns, can serve as a tool to define
66 the core calling periods of the species recorded (Lemckert and Mahony, 2008), for which
67 it is considered of utmost importance to increase the detection probability in anuran
68 survey programs. The use of automated recording devices for passive acoustic monitoring
69 techniques (PAM) can add valuable information such as the acoustic breeding patterns,
70 as several species of anurans may breed simultaneously in different reproductive sites
71 (Nelson and Garcia, 2017; Duarte *et al.*, 2019; Ulloa *et al.*, 2019; Pérez-Granados *et al.*,
72 2020).

73 Amphibians are suffering alterations in their phenological patterns because of the
74 increasingly frequent extreme climatic events caused by the global climate crisis (Lanno
75 and Stiles, 2020). This is particularly concerning for the species distributed throughout

76 the biodiversity hotspot of the tropical Andes of South America (Myers *et al.*, 2000),
77 which are severely affected by the consequences of climate change (Burrowes, 2008). In
78 addition, in times of the global diversity crisis, amphibians are considered the most
79 affected groups among terrestrial vertebrates (Stuart *et al.*, 2004; IUCN, 2023).

80 Based on the temporal pattern of their breeding phenology, anurans have been
81 historically classified into two discrete groups, as proposed by Wells (1977): explosive
82 breeders and prolonged breeders. Although there is a behavioural continuum between
83 these two extremes (Wells, 1977; 2007). In recent years, several works focused on better
84 describing the breeding acoustic strategies that can be found in anuran species (Chen *et*
85 *al.*, 2023; Donnelly and Guyer, 1994; Forti *et al.*, 2022; Huang *et al.*, 2001; Prado *et al.*,
86 2005; Prasad *et al.*, 2022; Bertoluci and Rodrigues, 2002) but there is still missing
87 information mainly for Neotropical anurans. Continuous monitoring of anuran
88 advertisement calls along different spatial-temporal scales, can provide valuable
89 information about the different breeding strategies displayed by each species in an
90 assemblage (Moreira *et al.*, 2007).

91 The acoustic niche hypothesis (Krause, 1987) proposes that each individual
92 elaborating messages through sound in each environment will present a partition in its
93 spectral and temporal features, to avoid being masked by others (Krause, 1993). In
94 species-rich assemblages from different clades, different strategies are expected to be
95 present to avoid the competition in the acoustic communication channel (Bertolucci and
96 Rodrigues, 2002; Herrick *et al.*, 2018; Klump and Gerhardt, 1992). One way to minimize
97 competition for the acoustic space is made effectively by segregating the niche in its
98 temporal and spectral dimensions (Both and Grant, 2012; Sinsch *et al.*, 2012; Guerra *et*
99 *al.*, 2020, Lima *et al.*, 2019). The temporal segregation of the advertisement calls can be
100 fundamental for the constitution of large anuran assemblages, mainly in breeding areas

101 where several species vocalize simultaneously (Drewry and Rand, 1983; Schwartz and
102 Wells, 1983; Bertolucci and Rodrigues, 2002; Duarte *et al.*, 2019).

103 The Yungas ecoregion is one of the most biodiverse environments in Argentina
104 (Brown *et al.*, 2006) harbouring up to 40 species of anurans (Lavilla and Heatwole, 2010).
105 These subtropical montane forests are characterized by a steeped altitudinal gradient
106 described by phytogeographic stratum (Grau and Brown, 2000). The anuran assemblages
107 that inhabit the subtropical montane forest of the Parque Nacional Calilegua (PNC) within
108 the Yungas ecoregion, was reported to present a wide range of temporal and spatial
109 breeding patterns ranging from opportunistic to prolonged breeders (Vaira, 2002).
110 However, these records of breeding activity were obtained based on regular monthly
111 surveys lasting from 3 to 5 days carried out through active searches by visual and acoustic
112 sampling (Vaira, 2002). The anuran assemblage of the PNC is composed by a few
113 endemic species to the Yungas ecoregion and by numerous species with a wide
114 distribution in Argentina and other South American countries (Lavilla, 2001; Vaira *et al.*,
115 2017). In addition, a low number of studies aimed to describe and understand the
116 complete acoustic breeding phenology over an entire year in neotropical anurans
117 (Bertolucci and Rodrigues, 2002; Prado *et al.*, 2005; Saenz *et al.*, 2006). Therefore, there
118 are still wide gaps of information about the daily and annual patterns of calling activity
119 and the breeding acoustic phenology of the anuran species that conforms different
120 assemblages inhabiting the Yungas forests.

121 A recent study suggests the use of PAM as an effective technique to monitor the
122 species of anurans in the Yungas forests (Boullhesen *et al.*, 2021). In addition, with the
123 implementation of a PAM program, researchers were able to discover hidden behavioural
124 insights of phenological activity, such as the nocturnal calling activity of a frog species

125 inhabiting the Yungas forests, that was previously considered as a strictly diurnal species
126 (Pereyra *et al.*, 2016).

127 In this study, we describe the daily and annual patterns of calling activity of the
128 anuran assemblages inhabiting the Yungas Andean Forests using PAM. Furthermore, we
129 propose a new classification scheme for the acoustic breeding strategies used by different
130 species of Neotropical anurans. Also, we aim to explore the occupation level of the
131 acoustic communication channel and to determine the temporal overlap of the acoustic
132 niche of this subtropical anuran assemblage.

133

134 MATERIALS AND METHODS

135

136 *Study sites and data collection*

137 A PAM was carried out for 12 months (from September 2017 to August 2018) along an
138 altitudinal gradient in the PNC, being the most representative portion of the Yungas
139 ecoregion in Jujuy province, Argentina. The PNC harbours the phytogeographic strata
140 described for the Yungas forests as well as different environments where anurans breed
141 (Vaira, 2002). The study was carried out in the three main forest types described for the
142 ecoregion: Premontane Lowland Forests (400 - 700 m a.s.l.) which is a semideciduous
143 environment with a marked seasonality, the understory consists of dense bushes, herbs,
144 ferns and lianas; Lower Montane Forests (700 - 1300 m a.s.l.) dominated by evergreen
145 trees such as *Juglans australis*, *Cedrella balansae* and *Enterolobium contortisiliquum*;
146 the Upper Temperate Montane Forests (1500 – 2500 m a.s.l.) which is a primary old forest
147 dominated by trees from Myrtacea family (Grau and Brown, 2000). The two upland forest
148 types have markedly more moisture than the lower forests. Three automated recording
149 units Song Meter 4 (Wildlife Acoustics Inc., Concord, Massachusetts), one per site were

150 installed and programmed to record 3 minutes per hour (24/7) (Shirose *et al.*, 1997;
151 Márquez *et al.*, 2014). Recordings were done in MONO channel using in-built low noise
152 microphones and stored in 32GB SDXC Flash Cards in .WAV format. The recorders were
153 placed at 1.5 m above ground in three sites: Premontane Forest (PF) (23°45'16.84" S;
154 64°50'59.35" W, 650 m a.s.l.), at the edge of a permanent pond with an approximate area
155 of 1114 m². The Lower Montane Forest (LMF) (23°41'36.84"S; 64°52'5.04" W, 1125 m
156 a.s.l.), at the edge of a permanent stream and in Upper Montane Forest (UMF) (23°40
157 '28.56"S; 64°53'44.15" W, 1750 m a.s.l.), attached to a tree near temporary ponds.
158 Recorders were visited monthly to data download and battery replace. These locations
159 are representative to the breeding areas used by the anuran assemblage of the region
160 (Vaira, 2002).

161

162 *Data Analysis*

163 13,485 recordings were listened corresponding to one day per week (= 224.75 hours) from
164 the three study sites together throughout a year-round monitoring. Recordings were
165 inspected manually by a trained specialist in anurans call recognition of Yungas forests
166 (MB) in Raven Pro 1.5 (Bioacoustics Research Program, 2014) using a window type =
167 Hann, DFT size = 512 samples, and overlap = 50%. For the general description of the
168 acoustic phenology of the anuran species recorded, the monitored year was divided in two
169 seasons (six months each) marked by the regional climate as follows: A) spring-summer
170 season, corresponding to the period from September 2017 to March 2018. B) fall-winter
171 season, corresponding to the period from March 2018 to September 2018.

172 To describe the annual acoustic phenology, we used the classification of core
173 calling periods proposed by Lemckert and Mahony (2008). This considers the core calling
174 period for each species as the time-period containing > 90 % of the calling events. For

175 these classifications we considered the species with a total of ≥ 50 calling events records
176 only. With the data of the calling events per-day recorded throughout the year-round study
177 we conducted a bottom-up hierarchical cluster analysis using *vegan* and *cluster* R
178 packages. For this analysis euclidean distance and complete method were employed after
179 correlation checking of the cophenetic distance obtained with the original data used
180 (>0.90). This analysis was implemented in free software R.

181 To describe the daily and annual vocal activity of each species we adapted the
182 classification proposed by Bridges and Dorcas (2000) as follows: 0 = no male vocalizing;
183 1 = one male vocalizing; 2 = multiple males vocalizing with the possibility of occasionally
184 distinguishing single calls; 3 = multiple males vocalizing but unable to distinguish single
185 calls. We considered each advertisement call detected from a recording as a “calling
186 event”, since we could not assign a distinct call to an individual. Circular statistics was
187 employed to describe and analyse the daily calling patterns (Jammalamadaka *et al.*, 2001;
188 Pewsey *et al.*, 2013). Rayleigh test was applied to explore whether the population of
189 circular data, from which a sample is drawn, differs from randomness (Wilkie, 1983).

190 To explore temporal niche overlap in calling activity, we computed the Pianka
191 (Pianka, 1973) and Czekanowski indices (Feinsinger *et al.*, 1981) using the TimeOverlap
192 program (Castro-Arellano *et al.*, 2010; Guerra, 2020). The Czekanowski index or
193 Proportional Similarity Index varies between 1 (widest amplitude of the niche where the
194 population exploits the resources in proportion to their availability) and 0 (where the
195 population specializes in the rarest state of a resource and skip the other items). Whereas
196 the Pianka index can return values less than zero (allowing for a coexistence between
197 species) or greater than one (promoting a competition between species).

198 To characterize the use of the acoustic communication channel in anurans recorded,
199 the methodology proposed by Emmrich *et al.* (2020) was used according to their acoustic
200 calls features where:

201 Guild A = unmodulated simple call

202 Guild B = modulated simple call

203 Guild C = unmodulated pulsed call

204 Guild D = modulated pulsed call

205 Guild E = unmodulated pulsed multi-note call

206 Guild F = uniform modulated pulsed multi-note call

207 Guild G = non-modulated different multi-notes call

208 Guild H = modulated different multi-notes call

209

210 These guilds groups were previously visualized using clean calls from each species
211 recorded with the seewave package in R using a Hanning type windows, 75 % overlap
212 and 1024 sample size (Figure S1).

213

214 RESULTS

215

216 *Annual Calling Periods*

217 A total of 3318 calling events of anuran species were recorded in the three study sites
218 within the Calilegua National Park (Figure 1). We detected calling activity throughout
219 the entire year (Figure 1), with a minimum of one species vocalizing in the driest months
220 of July and August and a maximum of 16 species vocalizing simultaneously during
221 December (Figure 1). Most of the calls were recorded during the hottest and rainy period

222 (spring-summer seasons), with peaks of calling activity during November, December, and
223 January (Tables 1 and 2).

224 *Boana riojana* was the only species recorded throughout the year-round
225 monitored and presented high records in the fall-winter period (Figure 1). Meanwhile, the
226 rest of the species from Hylidae family were recorded calling over the spring-summer
227 period (Figures 1-2). Most of the species from Leptodactylidae family were recorded
228 calling at spring-summer periods, with the summer period having the highest core calling
229 periods. However, *Pleurodema borellii* presented peaks of calling activity in the fall-
230 winter period (Figure 1). The two toads of the genus *Rhinella* were registered calling
231 during the early spring-summer period. Meanwhile *Melanophryniscus rubriventris* was
232 recorded vocalising in the spring-summer, but also detected in the early dry-cold fall-
233 winter period (Figure 1). The direct development-frogs from Craugastoridae family
234 presented calling records concentrated in the spring-summer period, mainly during the
235 summer season (Figure 1-2). The unique arboreal specie from Phyllomedusidae family
236 (*P. boliviana*) presented calling records concentrated in the summer season (Figure 1-2).

237

238 *Acoustic Breeding Strategies*

239 The cluster analysis revealed five different acoustic breeding strategies (Figure 3):
240 continuous breeders, prolonged non-seasonal breeders, prolonged seasonal breeders,
241 prolonged non-regular breeders, and sporadic seasonal breeders.

242 A continuous breeding strategy was found in males of *Boana riojana*, who
243 vocalized during all months of the year. A prolonged non-seasonal breeding pattern was
244 observed in *Pleurodema borelli*, which started calling in spring-summer and continued
245 through the fall-winter period. Prolonged seasonal breeders were clustered into two
246 subgroups: prolonged-regular breeders called evenly spaced throughout the breeding

247 season (spring - summer period), presenting many calling events records; prolonged non-
248 regular breeders had a calling activity spaced throughout the summer season. Sporadic
249 seasonal breeders were found in 9 species belonging to 5 different families, which called
250 sporadically during the spring-summer period only (Figure 3).

251

252 *Daily calling patterns*

253 Species of the family Bufonidae presented highly contrasting daily calling patterns.
254 Species of the genus *Rhinella* presented a mainly crepuscular and nocturnal calling
255 pattern; *R. arenarum* presented a peak of activity at 20:00 h, while *R. diptycha* vocalised
256 mainly between 20:00 h and 21:00 h (Rayleigh = 0.77; $p = 0.0002$; Rayleigh = 0.93; $p =$
257 0.0001) (Table 1, Figure 4). Meanwhile, *Melanophryniscus rubriventris* was mainly a
258 diurnal species, with peaks of vocal activity at 06:00 h and 18:00 h (Rayleigh = 0.52; p
259 <0.0001) (Table 1, Figure 4).

260 The species of the family Hylidae at the PF site recorded a mainly crepuscular-
261 nocturnal vocal activity, although sporadic calling activity was detected during the day.
262 *Boana riojana* was recorded at PF and at the LMF sites, at the PF site presented a mainly
263 nocturnal calling activity, with peaks of vocal activity at 01:00 h and 03:00 h; meanwhile,
264 at the LMF site, with a higher number of records, presented a mainly nocturnal calling
265 pattern, but also with diurnal vocalizations (Table 1, Rayleigh = 0.8; $p < 0.0001$).
266 *Dendropsophus nanus* presented a crepuscular-nocturnal vocal activity, with separated
267 activity peaks at 20:00 h, 21:00 h, and 05:00 h (Rayleigh = 0.65; $p <0.0001$). *Scinax*
268 *fuscovarius* presented a calling pattern mainly crepuscular and nocturnal, with a peak of
269 records at 22:00 h and 06:00 h, but also presented vocalizations during the day at 14:00
270 and 17:00 h (Rayleigh = 0.42, $p <0.0001$). By the other hand, *S. nasicus* presented a more
271 sporadic and nocturnal vocal activity, with peaks at 22:00 h and 23:00 h (Rayleigh = 0.8,

272 $p = 0.005$). *Trachycephalus typhonius* had a mainly crepuscular activity, with a peak of
273 activity at 20:00 h, and was also recorded calling during the day at 14:00 h (Rayleigh =
274 0.59, $p = 0.007$).

275 The species of the family Craugastoridae presented a daily vocal pattern but was
276 mainly crepuscular-nocturnal. *Oreobates barituensis* presented a sporadic pattern during
277 the day with records of calls from 17:00 h to 20:00 h, with a peak of vocal activity at
278 05:00 h (Rayleigh = 0.5; $p < 0.0002$) (Table 1, Figure 4). *Oreobates berdemenos* presented
279 markedly crepuscular-nocturnal vocal activity with a peak of vocal activity between
280 05:00 h and 06:00 h but was recorded vocalizing continuously during the 24 hs of the day
281 (Rayleigh = 0.3; $p < 0.0001$).

282 Species of the family Leptodactylidae presented a mostly crepuscular-nocturnal
283 daily vocal pattern, but records of calling activity were also detected during the day for
284 some species. *Leptodactylus apepyta* began to vocalize at 19:00 h in the evening and
285 peaked at 20:00 h and at 21:00 h (Rayleigh = 0.75; $p < 0.0001$). *Leptodactylus*
286 *macrosternum* presented a mainly nocturnal calling activity with a peak between 24:00
287 and 01:00 h but also was recorded calling during the daytime, frequently between 06:00
288 h and 08:00 h (Rayleigh = 0.59; $p < 0.0001$). *Leptodactylus elenae* called mainly at night,
289 presenting peaks of calling activity at 22:00 h and at 01:00 h (Rayleigh = 0.68; $p < 0.0001$).
290 *Leptodactylus fuscus* presented a mainly nocturnal vocal activity, with sporadic peaks at
291 21:00 h and between 05:00 h and 06:00 h, with sporadic records during the daytime
292 (Rayleigh = 0.66, $p < 0.0001$). *Leptodactylus gracilis* was recorded even more
293 sporadically, mainly at twilight, with a peak at 20:00 h (Rayleigh = 0.69; $p = 0.0009$).
294 *Leptodactylus latinasus* presented a twilight-nocturnal vocal activity, beginning to call at
295 19:00 h, with extensive records during the last hours of the night and a peak of calling
296 activity at 20:00 h (Rayleigh = 0.74; $p < 0.0001$) (Table 1, Figure 4). *Phyllomedusa*

297 *boliviana*, an arboreal species, presented a strictly nocturnal vocal activity, with records
298 of calls at 21:00 h and at 02:00 h, and a peak of calling at 22:00 h (Rayleigh = 0.81; $p < 0$,
299 0001) (Table 1, Figure 4).

300

301 *Temporal niche overlap*

302 The annual temporal niche overlap, and the spring-summer season overlap of the recorded
303 species, was moderately high at PF site according to Pianka's index. According to the
304 Czekanowski's index, the use of the temporal acoustic space was equitable (Czekanowski
305 ~ 0.5) in the species assemblage recorded at the same site, both for the entire year and
306 during the highest records of vocal activity in spring-summer season (Table 2).
307 Meanwhile, the temporal niche overlap was lower in the LMF and UMF sites (Table 2),
308 according to the Pianka's index (Table 2). In addition, the time niche overlap during the
309 fall-winter season was moderate at LMF, according to the Pianka's index (Table 2).
310 According to the Czekanowski's index, a temporal niche overlap was found to be greater
311 than that expected by chance (coincident activity) in the spring-summer period in the
312 species that vocalize at the LMF site (Table 2).

313

314 *Calling guilds*

315 Six different calling guilds were recorded based on their advertisement calls features
316 (Table 3; Figure S1). *Leptodactylus aepyta*, was the only representative of the calling
317 guild "A"; *L. elenae*, *L. fuscus*, *L. latinasus*, *Physalaemus cuqui* and *Trachycephalus*
318 *typhoni*, were framed within the calling guild "B". *Rhinella arenarum* and *R. dypticha*
319 were part of the guild "D". *Oreobates barituensis* was the only representative of the
320 calling guild "E". *Boana riojana*, *Dendropsophus nanus*, *L. gracilis*, *Oreobates*
321 *berdemenos*, *Phyllomedusa boliviana*, *Pleurodema borellii*, *Scinax fuscovarius*, *S.*

322 *nasicus* were part of the largest recorded group, the calling guild “F”. *Leptodactylus*
323 *macrosternum* and *Melanophryniscus rubriventris* formed the calling guild “G”.

324

325

DISCUSSION

326

327 In this study, the calling phenology of anuran species is described at a fine timescale
328 (hourly and daily) and quantitatively assessed along an altitudinal gradient in three
329 Andean Montane Forest ecosystems of the Yungas ecoregion, within the PNC. This level
330 of detail enabled us to propose a new classification scheme of acoustic breeding strategies
331 according to the time spent by each species calling throughout a year.

332 Previous breeding strategies classification schemes were used to describe the
333 breeding patterns of anuran species in the Calilegua National Park, following Duellman
334 and Trueb (1986). Following this previous classification scheme only two breeding
335 strategies were recorded for the entire species assemblage in this protected area (Vaira,
336 2002). Prado *et al.* (2005) described three reproductive activity patterns for a diverse
337 anuran assemblage in a floodplain in the Pantanal region of Brazil. With the use of
338 automatic recorders Saenz *et al.* (2006) were able to classify the anuran breeding activity
339 patterns in: explosive breeders, winter breeders, summer breeders and continuous
340 breeders depending on the core calling period recorded. Kopp *et al.* (2010) identified up
341 to four distinct anuran reproductive patterns recorded by 13 visual encounter surveys in
342 the Cerrado of Brazil. In this study, with the implementation of a PAM over an entire year
343 we were able to identify five distinct breeding acoustic patterns and provide a novel,
344 standardized classification framework, so that it can be tested in other ecosystems.

345 The great majority of the species recorded in this study showed a markedly seasonal
346 breeding acoustic pattern, with their core calling periods centred during the spring-

347 summer season in agreement with the warm and rainy season. These records were also
348 reported by a previous study conducted on the same assemblage 20 years ago (Vaira,
349 2002). However, we now provide a detailed acoustic breeding phenology of the anuran
350 species inhabiting three phytogeographical strata of the Yungas Andean Forest. The
351 marked seasonal acoustic pattern might be related to the breeding behaviour present in
352 these species that mainly use lentic waterbodies for their reproduction, with free-living
353 tadpoles (Vaira *et al.*, 2002; Pereyra *et al.*, 2018; Boullhesen *et al.*, 2019).

354 Strictly sporadic seasonal breeders were found in the families Bufonidae,
355 Leptodactylidae, and Strabomantidae, with one to four calling events per month. The
356 calling activity recorded for sporadic-breeding species in a tropical forest of Guyana
357 lasted between one and three consecutive nights (Gottsberger and Gruber, 2004). The
358 records of calls from explosive breeders were in coincidence with the warm and rainy
359 period of the study. The calling activity of explosive breeders has been documented to
360 correlate positively with temperature and rainfall cues in tropical anuran assemblages that
361 use ephemeral ponds (Ulloa *et al.*, 2019). Similarly, another study described the explosive
362 breeders to call in the rainy season in the Pantanal of Brazil (Prado *et al.*, 2005).

363 Prolonged seasonal breeders were the most representative groups in the study area.
364 In another study along an altitudinal gradient of Brazil this reproductive pattern was also
365 predominant among anuran species whose calling activity was recorded for 6 months
366 (Arzabe, 1999). These temporal reproductive patterns agreed with others already reported
367 for the Yungas forests (Vaira, 2002; Akmentins *et al.*, 2015; Pereyra *et al.*, 2018). The
368 species of the family Leptodactylidae are mainly prolonged breeders, calling throughout
369 the night and with sporadic calling activity during the day in representatives of the genus:
370 *Leptodactylus*, *Physalaemus*, and *Pleurodema* (Vaira, 2002; Camurugi *et al.*, 2017;
371 Boullhesen *et al.*, 2019). However, it should be noted that certain species of the family

372 such as *Leptodactylus fuscus* were characterized as mainly nocturnal in other ecoregions
373 (Lucas *et al.*, 2008; Guerra *et al.*, 2020), although they showed an extended pattern of
374 calling activity in daylight time recorded by a PAM in the Yungas ecoregion (Boullhesen
375 *et al.*, 2019). Our work provides novel information about the acoustic phenology patterns
376 of a recently described species, *L. aepelyta*, calling in the summer season showing a
377 crepuscular-nocturnal activity where males vocalize outside subterranean nests that they
378 built near the edge of temporary ponds (Schneider *et al.*, 2019).

379 The tree frog *Boana riojana* was the only continuous breeder recorded in the study
380 area calling throughout every month of the year. Duellman (1970) suggested that the
381 hylids of Central America reproduce continuously throughout the year if the
382 environmental conditions are favourable. In addition, these records may, in turn, be linked
383 to the characteristics of the monitored site. For example, the site LMF is characterized by
384 abundant vegetation (evergreen forest) and a permanent mountain stream, providing
385 optimal conditions for *B. riojana* to vocalise and breed throughout the entire year. In other
386 species of this genus, a continuous breeding strategy has been suggested to correlate with
387 adult male gravid and post metamorphic females' abundances recorded throughout a year
388 of survey (Hiert and Moura, 2010). Previous research suggested that the members of the
389 family Hylidae have a crepuscular-nocturnal vocal activity (Guerra *et al.*, 2020).
390 However, our PAM study showed that *B. riojana* also calls during daylight, thus
391 suggesting a more plastic calling behaviour in this species. There are reports of diurnal
392 movement in species of the genus *Boana* in temperate forests of Brazil (de Oliveira *et al.*,
393 2016). Therefore, it is interesting to explore the vocal repertoire of *B. riojana*, to
394 determine if these daytime vocalizations correspond to advertisements calls or other types
395 of vocalizations, such as territorial interactions or rain calls (Toledo *et al.*, 2015).

396 The anuran assemblage recorded in this study presented a slight temporal acoustic
397 niche overlap (time spent calling), mainly in the site with the highest diversity of species
398 (PF). In addition, the temporal overlap of advertisement calls detected during the spring-
399 summer period in the LMF site is remarkable. These results are in contrast with those
400 reported for congeneric syntopic species that reproduce in permanent water bodies in the
401 Cerrado savanna of Brazil (Guerra *et al.*, 2020). The high diversity of species that
402 compose the assemblages of the Yungas forests (Lavilla and Heatwole, 2010; Vaira *et*
403 *al.*, 2017), suggests that in places where several species reproduce simultaneously, the
404 greatest diversity of calling patterns should be found to avoid being masked by others
405 (Bertoluci and Rodrigues, 2002; Herrick *et al.*, 2018; Klump and Gerhardt, 1992). The
406 classification of advertisement calls of anurans, according to their spectral parameters in
407 guilds, enables the comparison between groups of species to be faster and easier
408 (Emmrich *et al.*, 2020). This variety of acoustic strategies can be seen reflected in the
409 calling guilds diversity detected in this study, mainly in the assemblage belonging to the
410 PF site, with a total of five calling guilds recorded. Nevertheless, the calling guild with
411 modulated pulsed multi-note calls was the most representative of the study, and unlike
412 other guilds detected where there is a strong phylogenetic signal, this guild is made up of
413 species from five different families. This observed pattern may conform with the Public
414 Information Theory where anuran species with different phylogenetic relatedness
415 elaborate advertisement calls with similar acoustics features (Danchin *et al.*, 2004;
416 Goodale *et al.*, 2010; Sugai *et al.*, 2021). In this sense, the anuran species belonging to
417 different lineages could be using the same venue for information to determine the optimal
418 conditions to breed. Thus, enabling an inadvertent social information resource available
419 and driving the species to use similar acoustic traits (Danching *et al.*, 2004; Goodale *et*
420 *al.*, 2010).

421 The PAM employed in this study allowed us to describe in detail the acoustic
422 reproductive patterns in an anuran assemblage in the mountain forests of the southern
423 Yungas of north-western Argentina. This information made it possible to extend the
424 previous knowledge regarding the calling activity of the species, contributing
425 quantitatively to a better knowledge of a key aspect in the life history for each species
426 recorded (calling activity), and to add new data for several secretive species.

427 In addition, it was possible to better characterize the variety of calling breeding
428 strategies of the species recorded and, describe a standardized classification scheme to be
429 tested in other ecosystems employing PAM method. In addition, we were able to access
430 precise information on the temporal daily and seasonal acoustic distribution of the
431 recorded anuran assemblage. This data is valuable and may be of great importance for
432 implementing monitoring programs of anuran diversity in the Andean regions of South
433 America.

434

435 ACKNOWLEDGMENTS

436 We thank Dirección Regional Noroeste of the Administración de Parques Nacionales
437 (APN DRNOA) for providing MB with the research permits in the Calilegua National
438 Park (118/2017 Rnv. 1). We thank The Rufford Foundation for awarding MB a Rufford
439 Small Grant (Project ID- 22246-1). We thank CONICET for a full scholarship awarded
440 to MB. The present work was partially supported by PIO CONICET 094 and PUE
441 INECHOA 22920170100027CO.

UMF	Fall-Winter	-	-	-	-

695

696

697 **Table 3.** Calling guilds recorded along an altitude gradient within the Parque Nacional
698 Calilegua, Argentina: permanent pond in the premontane forest (PF, 650 m a.s.l.),
699 permanent stream in lower montane Forest (LMF, 1125 m a.s.l.), and upper montane
700 forest (UMF, 1750 m a.s.l.). Total number of species recorded n = 19. Guild A =
701 unmodulated simple call; Guild B = modulated simple call; Guild C = unmodulated
702 pulsed call; Guild D = modulated pulsed call; Guild E = unmodulated pulsed multi-note
703 call; Guild F = uniform modulated pulsed multi-note call; Guild G = non-modulated
704 different multi-notes call; Guild H = modulated different multi-notes call.

Guilds	N° of recorded species	Percent	PF	LMF	UMF
A	1	5.26 %	1	-	-
B	5	26.31 %	5	-	-
C	-	-	-	-	-
D	2	10.52 %	2	-	-
E	1	5.26 %	1	1	-
F	8	42.10 %	7	2	1
G	2	10.52 %	1	-	1
H	-	-	-	-	-

707

CAPTIONS TO FIGURES

708

709

710 **Figure 1.** Total number of calling events recorded for anuran species in the Parque
711 Nacional Calilegua spanning the three sites together. Grey squares indicate calling
712 activity. Dark squares indicate core calling periods.

713

714 **Figure 2.** Records of calling activity in the anuran assemblage of the Parque Nacional
715 Calilegua. Black cells = maximum call events registered (3). Grey cells = medium calling
716 events registered (2). Light cells = minimum callings events registered (1). PF =
717 premontane forest; LMF = lower montane forest; UMP = upper montane forest.

718

719 **Figure 3.** Dendrogram showing the bottom-up hierarchical cluster analysis in the species
720 recorded at the Parque Nacional Calilegua. Colours represent the five acoustic breeding
721 strategies obtained.

722

723 **Figure 4.** Rose diagrams showing daily calling activity of recorded species in the study
724 sites. Dotted lines = Kernel data distribution.
