Hoveyda-Grubbs second generation catalysts
Tetrasubstituted alkenes
Configuration assignment
X-ray diffraction analyses

#### Abstract

The cross metathesis (CM) of several methylenecyclopentane derivatives using Hoveyda-Grubbs second generation catalyst $4(5-10 \mathrm{~mol} \%$ ) has been studied. Medium to good yields of tetrasubstituted alkenes have been obtained. In the case of 8-methyl-2,5-dimethylene-2,3,5,6-tetrahydro-1H,4H-3a,6a-(meth-anoiminomethano)pentalene-7,9-dione 2 products from single, double and triple CM were formed. With 8-methyl-5-methylene-5,6-dihydro-3a,6a-(methanoiminomethano)pentalene-2,7,9(1H,3H,4H)-trione 3 a good yield of the CM product was obtained working at $140{ }^{\circ} \mathrm{C}$ in xylene for 3 d , showing the high thermal stability of this catalyst. In the CM of diene 2 and enone 3, the main products were always the anti-stereoisomers.

## 1. Introduction

In the last decade, the metathesis of olefins has become a very convenient method to prepare many kinds of alkenes, ${ }^{1-9}$ and a key retrosynthetic pathway in the design of many organic syntheses. ${ }^{10-14}$ Many di- and tri-substituted alkenes can be obtained by olefin metathesis. Also, several tetrasubstituted alkenes have been obtained by ring closing metathesis (RCM). ${ }^{15-21}$ However, to the best of our knowledge, only a group has described the formation of tetrasubstituted alkenes by cross metathesis (CM), one of the partners being an $\alpha$-methylene- $\beta$-lactam. ${ }^{22,23}$

We have recently described a one-step preparation of several methylenecyclopentane derivatives, such as compounds 1 and 2 from $N$-methylsuccinimide and 3-chloro-2-chloromethyl-1-propene. ${ }^{24}$ Also, we have been interested for a long time in the preparation of belt compounds of general structure 6. ${ }^{25-28}$ Consequently, we considered of interest to study the CM of $\mathbf{1}$ (as a model compound), $\mathbf{2}$ and derivatives, such as $\mathbf{3}$, as a possible way to prepare compounds 6 (Fig. 1).

[^0]
## 2. Results and discussion

As a model reaction, compound 1 was heated in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ under an Ar atmosphere for 6 h plus 3 d at room temperature, in the presence of the Hoveyda-Grubbs second generation catalyst (4,5\% molar ratio), leading to a mixture of CM products anti or $Z 7$ and syn or $E 8$ (approximate ratio $7 / 8=1: 2$ ) in $48 \%$ yield, much starting compound being recovered (Scheme 1 ). When this reaction was carried out at $45^{\circ} \mathrm{C}$ for 66 h , the yield of mixture $7+\mathbf{8}$ increased till $79 \%$, the ratio $\mathbf{7 / 8}$ being essentially the same. Pure samples of both stereoisomers could be isolated by silica gel column chromatography and were fully characterized, the stereochemistry of 7 and 8 was assigned on the basis of their epoxides.

Epoxidation of 7 gave only one epoxide 9 with $C_{S}$ symmetry [10 ${ }^{13} \mathrm{C}$ NMR and $7{ }^{1} \mathrm{H}$ NMR signals: the signals of $4(6)-\mathrm{H}_{\mathrm{x}}$ and $4{ }^{\prime \prime}\left(6^{\prime \prime}\right)-\mathrm{H}_{\mathrm{x}}$ appear overlapped]. The structure of this epoxide was clearly established by X-ray diffraction analysis (Fig. 2). ${ }^{29}$ Consequently, the CM product 7 must be the ( $Z$ )-stereoisomer with $C_{2 h}$ symmetry, whose epoxidation can give only one epoxide. The CM product 8 must be the $(E)$-stereoisomer with $C_{2 v}$ symmetry. Since its $C=C$ bond has diastereotopic faces, it might give two epoxides. However, epoxidation of $\mathbf{8}$ gave only one epoxide $\mathbf{1 0}$ that showed the same $C_{2 v}$ symmetry as $\mathbf{8}$ (five ${ }^{13} \mathrm{C}$ NMR and four ${ }^{1} \mathrm{H}$ NMR signals). The configuration of this epoxide was also established by X-ray

diffraction analysis (Fig. 3) ${ }^{29}$ as that shown in Scheme 1, being the epoxide oxygen atom opposed to the bridgehead H atoms.

Similarly, heating a solution of diene $\mathbf{2}$ in a closed vessel in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the presence of catalyst 4 ( $5 \%$ molar ratio) for 5 d at $45^{\circ} \mathrm{C}$, a mixture of the single CM product $\mathbf{1 1}$ together with products derived from the CM of three (12) or four (13) units of the starting compound $\mathbf{2}$, were obtained. These products were easily separated by silica gel column chromatography, isolating in order of elution, unreacted 2 ( $17 \%$ yield), 11 ( $29 \%$ yield), 12 ( $22 \%$ yield) and 13 ( $15 \%$ yield) (Scheme 2). Crude $\mathbf{1 1}$ was shown to be essentially only one stereoisomer, whose configuration was deduced to be anti or $Z$, as before, by chemoselective epoxidation of the more substituted $\mathrm{C}=$ C bond that gave epoxide $\mathbf{1 4}$ with $C_{S}$ symmetry [ $15{ }^{13} \mathrm{C}$ NMR (the carbonyl carbon atoms were not differentiated) and $12{ }^{1} \mathrm{H}$ NMR signals] (Scheme 2). The fraction containing the product derived from the condensation of three units of 2 (12) also corresponded mainly to only one stereoisomer ( ${ }^{13} \mathrm{C}$ NMR). Crystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}$ gave crystals adequate for X-ray diffraction analysis, which showed the product to be the anti,anti-stereoisomer, 12 (Fig. 4). ${ }^{29}$ Compound 13 derived from the condensation of four units of $\mathbf{2}$ showed to be only one stereoisomer to which the anti,-anti,anti-configuration was assigned on the basis of the established configuration of the formed $\mathrm{C}=\mathrm{C}$ bonds in compounds 11 and 12 and its $C_{2 h}$ symmetry ( $15{ }^{13} \mathrm{C}$ NMR and $11^{1} \mathrm{H}$ NMR signals).

We have also prepared enone $\mathbf{3}$ by controlled ozonization of $\mathbf{2}$, followed by reduction of the ozonide with dimethyl sulfide (Scheme 3). Under the optimized conditions, $\mathbf{3}$ was obtained in $42 \%$ yield, together with the known ${ }^{23}$ diketone 15 ( $33 \%$ yield) and starting diene 2.

Heating enone $\mathbf{3}$ in the presence of Hoveyda-Grubbs catalyst $\mathbf{4}$ ( $5 \%$ molar) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.09 \mathrm{mmol} \mathbf{3} / \mathrm{mL})$ at $45^{\circ} \mathrm{C}$ for 3 d in a closed vessel, a CM product 16 was obtained in only $4 \%$ yield (Scheme 4 ). When compound $\mathbf{3}$ was submitted to the above metathesis reaction conditions, but working in benzene at $80^{\circ} \mathrm{C}$ or in xylene at $130^{\circ} \mathrm{C}$, the yield of $\mathbf{1 6}$ increased to $20 \%$ and $40 \%$, respectively. When the reaction was carried out as before in xylene at $130^{\circ} \mathrm{C}$, but in a more concentrated solution ( $0.18 \mathrm{mmol} \mathbf{3} / \mathrm{mL}$ ), the yield increased to $45 \%$. Worthy of note, metathesis of $\mathbf{3}$ under the last conditions, but using Stewart-Grubbs catalyst ( $\mathbf{5}, 5 \%$ molar), which has been described as a better catalyst to prepare hindered alkenes, gave $\mathbf{6}$ in only $14 \%$ yield.

In the above reactions, part of the starting compound remained apparently unreacted (TLC). However, we established ( ${ }^{1} \mathrm{H}$ NMR) that working in xylene at $130^{\circ} \mathrm{C}$, the apparently unreacted compound $\mathbf{3}$ was in fact the isomerized product $\mathbf{1 8}$, inadequate for the desired metathesis. A sample of $\mathbf{1 8}$ was obtained by reaction of compound $\mathbf{3}$ with triflic acid in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution.

Since, the metathesis process may be reversible we carried out the reaction in xylene ( $0.18 \mathrm{mmol} 3 / \mathrm{mL}$ ) at $130^{\circ} \mathrm{C}$ for 3 d in an open vessel, always using catalyst $\mathbf{4}$ ( $5 \%$ molar) and in the presence of $p$ quinone to reduce the isomerization of the exocyclic $\mathrm{C}=\mathrm{C}$ bond, ${ }^{30}$ thus obtaining 16 in $50 \%$ yield. When the reaction was carried out under the above conditions in a more concentrated solution $(0.27 \mathrm{mmol} \mathbf{3} / \mathrm{mL})$, the yield of the above mixture increased to $65 \%$. Finally, under the optimum reaction conditions found till present, the yield increased to $66 \%$ of analytically pure product by working in xylene at $140{ }^{\circ} \mathrm{C}$ for 3 d in an open vessel at a concentration of $0.52 \mathrm{mmol} \mathrm{3} / \mathrm{mL}$. The main component of the obtained mixture could be isolated in pure form as a white solid by heating the mixture with MeOH and separating the solid product. As before, the anti or $Z$ configuration of the obtained product 16 was established by epoxidation, which gave epoxide 17 with $C_{s}$ symmetry ( $14{ }^{13} \mathrm{C}$ NMR and $10{ }^{1} \mathrm{H}$ NMR signals) (Scheme 4).

All of the new compounds described in this paper have been fully characterized on the basis of their spectroscopic data ( ${ }^{1} \mathrm{H}$ NMR, ${ }^{13}$ C NMR, IR), elemental analysis and accurate mass measurement.

Fig. 2. ORTEP of compound 9.

Fig. 3. ORTEP of compound 10.

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra have been assigned on the basis of ${ }^{1} \mathrm{H} /{ }^{1} \mathrm{H}$ homocorrelation spectra (COSY and NOESY), ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ heterocorrelation spectra [gHSQC (for one bond correlations) and gHMBC (for long range correlations)] and DEPT. Especially significant are the observed NOEs among protons of each diastereotopic moiety of epoxides 14 and 17 , which was the key to unequivocally assign the $Z$ configuration to their precursor alkenes, 11 and 16, respectively. Differentiation of the two moieties of epoxide 14 could be effected on the base of the NOE among $4(6)-\mathrm{H}_{\mathrm{n}}$ and $1^{\prime \prime}\left(3^{\prime \prime}\right)-\mathrm{H}_{\mathrm{x}}$, which is not possible among $4^{\prime \prime}\left(6^{\prime \prime}\right)-\mathrm{H}_{\mathrm{n}}$ and $1(3)-\mathrm{H}_{\mathrm{x}}$. The two moieties of epoxide 17 were assigned by comparison with the assignment carried out for epoxide 14.

## 3. Conclusion

In conclusion, Hoveyda-Grubbs second generation catalyst 4 has shown to be adequate for the CM of methylenecyclopentane derivatives $\mathbf{1}, \mathbf{2}$ and 3, with formation of tetrasubstituted alkenes working at temperatures as high as $140^{\circ} \mathrm{C}$. Worthy of note, the main CM products, 11, $\mathbf{1 2}$ and $\mathbf{1 3}$ derived from $\mathbf{2}$ and $\mathbf{1 6}$ derived from 3 has an anti-configuration for each formed $\mathrm{C}=\mathrm{C}$ bond.

## 4. Experimental section

### 4.1. General experimental methods

Melting points were determined in open capillary tubes. Except where otherwise stated, the NMR spectra were performed in $\mathrm{CDCl}_{3}$ at $400 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right.$ NMR $)$ and $100.6 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right.$ NMR). Chemical shifts ( $\delta$ ) are reported in parts per million ( ppm ) related to internal TMS or $\mathrm{CDCl}_{3}$. Multiplicities are reported using the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; m , multiplet; br, broad or their combinations. Assignments given for the NMR spectra are based on DEPT, ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ single quantum correlation (gHSQC sequence), ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ multiple bond correlation (gHMBC sequence) and Correlation SpectroscopY (COSY) experiments and also, for certain compounds, on Nuclear Overhauser Effect SpectroscopY (NOESY) information. Infrared spectra were obtained by using the Attenuated Total Reflectance (ATR) technique: Absorption values are given as wavenumbers $\left(\mathrm{cm}^{-1}\right)$, the intensity of the absorptions are given as strong ( s ), medium ( m ) or weak (w). High-resolution mass spectra (HRMS) were obtained with electrospray ionization using a TOF mass analyzer (ESI-MS) and are reported as $\mathrm{m} / \mathrm{z}$ (relative ratio). Column

chromatography was performed on silica gel 60 A C.C (35-70 mesh) or basic $\mathrm{Al}_{2} \mathrm{O}_{3}$ (Brockmann activity Grade 1). The eluents employed are reported as volume/volume ratio. For the thin layer chromatography (TLC), aluminium-backed sheets with silica gel

60 F254 were used and spots were visualized with UV light and/ or $1 \%$ aq $\mathrm{KMnO}_{4}$.

The oxygen/ozone stream used to prepare compound $\mathbf{3}$ was generated with a Fisher Ozon 500 equipment. An oxygen stream

to $45^{\circ} \mathrm{C}$ for 6 h under an Ar atmosphere and then the solution was magnetically stirred at room temperature for 3 d . The solvent was eliminated under reduced pressure and the brown oily residue ( 940 mg ) was subjected to column chromatography (silica gel $35-70 \mu \mathrm{~m}, 25 \mathrm{~g}$, hexane/EtOAc mixtures). In order of elution starting 1 ( 375 mg , hexane/EtOAc 85:15 till hexane/EtOAc 7:3) and a mixture of the CM products 7 and $\mathbf{8}$ ( 362 mg , hexane/EtOAc 1:1 till EtOAc), as a green-brown solid, were obtained. The above CM mixture was subjected to a new column chromatography (basic $\mathrm{Al}_{2} \mathrm{O}_{3}, 7 \mathrm{~g}$, hexane/EtOAc mixtures) to give a mixture of $\mathbf{7}$ and $\mathbf{8}$ in the approximate ratio 7/8 $=1: 2\left({ }^{1} \mathrm{H}\right.$ NMR $) ~(332 \mathrm{mg}, 48 \%$ yield, hexane/ EtOAc 7:3 till EtOAc) as a light brown solid. Crystallization of the above product from $\mathrm{MeOH}(7 \mathrm{~mL})$ gave the analytical sample of this mixture as a white solid, $\mathrm{mp} 179-181^{\circ} \mathrm{C}(\mathrm{MeOH})$. A part of the above mixture ( 147 mg ) was subjected to column chromatography (silica gel $35-70 \mu \mathrm{~m}, 20 \mathrm{~g}$, hexane/EtOAc mixtures). On elution with hexane/EtOAc 1:4, in order of elution, pure product $7(20 \mathrm{mg})$, a mixture of $\mathbf{7}$ and $\mathbf{8}(96 \mathrm{mg})$ and slightly impure $\mathbf{8}(26 \mathrm{mg})$ were

18

17

Scheme 4. Metathesis of compound $\mathbf{3}$ (arrows in compound $\mathbf{1 7}$ show significant NOEs. Geminal NOEs are not shown).
( $50 \mathrm{~L} / \mathrm{h}$ ) was passed through the ozonization equipment with a current of $0.20-0.22 \mathrm{~A}$, and a production potency of 1.1 , which corresponds to about 2.2 g ozone $/ \mathrm{h}$. Before starting the reaction, the oxygen/ozone stream was bubbled through $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ for about 10 min , till the $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ took a violet colour. In an empirical way, it was established that, under the above conditions, bubbling of the oxygen/ozone stream should last 10 min per gram of diene $\mathbf{2}$ in the solution.

Compound 2, obtained as described, ${ }^{23}$ contained about $11 \%$ of exocyclic $\mathrm{C}=\mathrm{C}$ bonds isomerized to an endocyclic position ( $\delta$ $\left.\mathrm{CH}=\mathrm{C}-\mathrm{CH}_{3}=1.71 \mathrm{ppm} ; \delta \mathrm{CH}=\mathrm{C}-\mathrm{CH}_{3}=5.43 \mathrm{ppm}\right)$. This product was purified by sublimation ( $60-100^{\circ} \mathrm{C} / 0.2-0.5$ Torr) and crystallization from a small amount of MeOH (three times), till a content of about $0.3 \%$ isomerized exocyclic $\mathrm{C}=\mathrm{C}$ bonds, before being used in the metathesis reaction. The mp of $\mathbf{2}$ increased from $91-92^{\circ} \mathrm{C}$, after sublimation, till $95-96.5^{\circ} \mathrm{C}$, after the third crystallization.

## 4.2. (3aR,3a'R,6aS,6a'S,Z) and (3aR,3a'R,6aS,6a'S,E)-2,2'-Di-methyl-3a, $3 a^{\prime}, 4,4^{\prime}, 6,6 a^{\prime}$-octahydro-1H, $1^{\prime}$ ' $-\left[5,5^{\prime}\right.$-bi(cyclopenta [c]pyrrolylidene)]-1, $1^{\prime}, 3,3^{\prime}\left(2 H, 2^{\prime} H\right)$-tetraone (7) and (8)

A solution of alkene $\mathbf{1}$ ( $758 \mathrm{mg}, 4.6 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(10 \mathrm{~mL})$ and ruthenium catalyst $\mathbf{4}(144 \mathrm{mg}, 0.23 \mathrm{mmol})$ was heated
obtained. The mixture of $\mathbf{7}$ and $\mathbf{8}(96 \mathrm{mg})$ was subjected to a new column chromatography (silica gel 35-70 $\mu \mathrm{m}, 15 \mathrm{~g}$, hexane/EtOAc mixtures). On elution with hexane/EtOAc 1:4, in order of elution, pure product $\mathbf{7}(12 \mathrm{mg})$, a mixture of $\mathbf{7}$ and $\mathbf{8}(55 \mathrm{mg})$ and slightly impure 8 ( 44 mg ) were obtained. The last fraction ( 44 mg ) was subjected to a new column chromatography (silica gel $35-70 \mu \mathrm{~m}$, 5 g , hexane/EtOAc mixtures) to give a mixture of $\mathbf{7}$ and $\mathbf{8}(18 \mathrm{mg}$, hexane/EtOAc 1:1) and pure $\mathbf{8}(24 \mathrm{mg}$, hexane/EtOAc 1:1-1:4).

When a similar reaction was carried out, starting from 1 ( $704 \mathrm{mg}, 4.26 \mathrm{mmol}$ ) and Ru catalyst $4(134 \mathrm{mg}, 0.21 \mathrm{mmol})$ in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and the solution was heated to $45^{\circ} \mathrm{C}$ for 66 h , after concentration and silica gel chromatography, mixtures of CM products 7 and $\mathbf{8}$ in different ratios were obtained ( $543 \mathrm{mg}, 79 \%$ global yield of the mixture, approximate global ratio $7 / \mathbf{8}=1: 2$ ).

Analytical and spectroscopic data of 7: $R_{f}=0.33$ (silica gel, 10 cm , EtOAc), mp 218-220 ${ }^{\circ} \mathrm{C}$ (hexane/EtOAc); IR (ATR) $\nu 2954$ (w), 2919 (w), 2829 (w), 1766 (w), 1693 (s), 1681 (s), 1449 (m), 1427 (m), 1380 (m), 1308 (m), 1280 (m), 1182 (w), 1158 (w), 1101 (m), 995 (m), $968(\mathrm{w}), 958(\mathrm{w}), 651(\mathrm{~m}), 611(\mathrm{~m}) \mathrm{cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR $\delta 2.57$ [d, $J=16.4 \mathrm{~Hz}, 4 \mathrm{H}, 4\left(4^{\prime}, 6,6^{\prime}\right)-\mathrm{H}_{\mathrm{x}}$ ], 2.62-2.72 [complex signal, 4 H , $4\left(4^{\prime}, 6,6^{\prime}\right)-\mathrm{H}_{\mathrm{n}}$ ], 2.95 (s, 6H, $2 \times N-\mathrm{CH}_{3}$ ), 3.24-3.30 [complex signal, $\left.4 \mathrm{H}, 3 \mathrm{a}\left(3 \mathrm{a}^{\prime}, 6 \mathrm{a}, 6 \mathrm{a}^{\prime}\right)-\mathrm{H}\right] ;{ }^{13} \mathrm{C}$ NMR $\delta 25.1\left(\mathrm{CH}_{3}, \mathrm{~N}-\mathrm{CH}_{3}\right)$, $33.5\left[\mathrm{CH}_{2}\right.$, C4( $\left.\left.4^{\prime}, 6,6^{\prime}\right)\right], 44.9$ [CH, C3a(3a',6a,6a')], 131.0 [C, C5(5 $\left.\left.5^{\prime}\right)\right], 179.8$ (C,

### 4.11. X-ray crystal-structure determination of compound 9

A prismatic crystal $(0.21 \times 0.367 \times 0.458 \mathrm{~mm})$ was selected and mounted on a D8 Venture diffractometer. Unit-cell parameters were determined from 9908 reflections ( $4.07<\theta<72.48^{\circ}$ ) and refined by least-squares method. Intensities were collected with graphite monochromatized $\mathrm{Cu} \mathrm{K} \alpha$ radiation, using $\omega / 2 \theta$ scantechnique. 13,737 reflections were measured in the range $5.02 \leq \theta \leq 72.48,2927$ of which were non-equivalent by symmetry ( $R_{\text {int }}($ on $I)=0.026$ ). 2653 reflections were assumed as observed applying the condition $I>2 \sigma(I)$. Lorentz-polarization and absorption corrections were made. The structure was solved by Direct methods, using SHELXS computer program and refined by fullmatrix least-squares method with SHELXLT computer program, ${ }^{31}$ using 13,737 reflections (very negative intensities were not assumed). The function minimized was $\Sigma w\left|F_{0}\right|^{2}-\left.\left|F_{c}\right|^{2}\right|^{2}$, where $w=$ $\left[\sigma^{2}(I)+(0.0557 P)^{2}+0.5162 P\right]^{-1}$, and $P=\left(\left|F_{0}\right|^{2}+2\left|F_{c}\right|^{2}\right) / 3, f, f^{\prime}$ and $f^{\prime \prime}$ were taken from International Tables of X-ray Crystallography. ${ }^{32}$ All H atoms were computed and refined, using a riding model, with an isotropic temperature factor equal to 1.2 time the equivalent temperature factor of the atom to which are linked. The final $R$ (on $F$ ) factor was 0.048 , $w R\left(\right.$ on $\left.|F|^{2}\right)=0.116$ and goodness of fit $=1.064$ for all observed reflections. Number of refined parameters was 209. Max shift/esd=0.00, mean shift/esd $=0.00$. Max and min peaks in final difference syntheses were 0.233 and -0.253 e $\AA^{-3}$, respectively (Table 1).

### 4.12. X-ray crystal-structure determination of compound $\mathbf{1 0}$

A prismatic crystal ( $0.1 \times 0.1 \times 0.2 \mathrm{~mm}$ ) was selected and mounted on a Bruker D8 Venture diffractometer. Unit-cell parameters were determined from 1350 reflections ( $4.24<\theta<39.23^{\circ}$ ) and refined by least-squares method. Intensities were collected with graphite monochromatized $\mathrm{Cu} \mathrm{K} \alpha$ radiation, using $\omega / 2 \theta$ scan-technique.

${ }^{\text {a }} \mu(\mathrm{Mo} \mathrm{K} \alpha$ ) linear absorption coefficient. Radiation $\operatorname{Mo} \mathrm{K} \alpha(\lambda=0.71073 \AA)$.
b $\mu(\mathrm{CuK} \alpha)$ linear absorption coefficient. Radiation $\mathrm{Cu} \mathrm{K} \alpha(\lambda=1.54178 \AA)$.
${ }^{\text {c }}$ Maximum peaks in final difference synthesis.
${ }^{\mathrm{d}}$ Minimum peaks in final difference synthesis.

4516 reflections were measured in the range $4.24 \leq \theta \leq 39.60$, 922 of which were non-equivalent by symmetry ( $R_{\text {int }}($ on $I)=0.058$ ). 719 reflections were assumed as observed applying the condition $I>2 \sigma(I)$. Lorentz-polarization and absorption corrections were made. The structure was solved by Direct methods, using SHELXS computer program and refined by full-matrix least-squares method with SHELX97 computer program, ${ }^{31}$ using 4516 reflections (very negative intensities were not assumed). The function minimized was $\Sigma w\left|\left|F_{0}\right|^{2}-\left|F_{c}\right|^{2}\right|^{2}$, where $w=\left[\sigma^{2}(I)+(0.0341 P)^{2}+3.3666 P\right]^{-1}$, and $P=\left(\left|F_{\mathrm{o}}\right|^{2}+2\left|F_{\mathrm{c}}\right|^{2}\right) / 3, f, f$ and $f^{\prime \prime}$ were taken from International Tables of X-ray Crystallography. ${ }^{32}$ All H atoms were computed and refined, using a riding model, with an isotropic temperature factor equal to 1.2 time the equivalent temperature factor of the atom, which are linked. The final $R$ (on $F$ ) factor was $0.055, w R$ (on $|F|^{2}$ ) $=0.101$ and goodness of fit $=1.108$ for all observed reflections. Number of refined parameters was 211. Max shift/esd $=0.00$, mean shift/ esd $=0.00$. Max and min peaks in final difference syntheses were 0.412 and $-0.104 \mathrm{e} \AA^{-3}$, respectively. The poor quality of reflections could be due to the fact that the crystal does not diffract very well. Other attempts of crystallization were done, but no single crystals of better quality were obtained (Table 1).

### 4.13. X-ray crystal-structure determination of compound 12

A prismatic crystal ( $0.1 \times 0.1 \times 0.2 \mathrm{~mm}$ ) was selected and mounted on a MAR345 diffractometer with an image plate detector. Unit-cell parameters were determined from 208 reflections ( $3<\theta<31^{\circ}$ ) and refined by least-squares method. Intensities were collected with graphite monochromatized Mo K $\alpha$ radiation. 25,109 reflections were measured in the range $1.31 \leq \theta \leq 32.40,8306$ of which were nonequivalent by symmetry ( $R_{\text {int }}$ (on $I$ )=0.076). 6005 reflections were assumed as observed applying the condition $I>2 \sigma(I)$. Lorentzpolarization and absorption corrections were made. The structure was solved by Direct methods, using SHELXS computer program, ${ }^{33}$
and refined by full-matrix least-squares method with SHELX97 computer program, ${ }^{33}$ using 25,109 reflections (very negative intensities were not assumed). The function minimized was $\Sigma w\left|\left|F_{0}\right|^{2}-\left|F_{\mathrm{c}}\right|^{2}\right|^{2}$, where $w=\left[\sigma^{2}(I)+(0.0957 P)^{2}\right]^{-1}$, and $P=\left(\left|F_{\mathrm{o}}\right|^{2}+2\left|F_{\mathrm{c}}\right|^{2}\right) /$ $3, f, f$ and $f^{\prime}$ were taken from International Tables of X-ray Crystallography. ${ }^{32} 29 \mathrm{H}$ atoms were located from a difference synthesis and refined with an isotropic temperature factor equal to 1.2 time the equivalent temperature factor of the atom, which are linked and 8 H atoms were computed and refined using a riding model with an isotropic temperature factor equal to 1.2 time the equivalent temperature factor of the atom, which are linked. The final $R$ (on $F$ ) factor was 0.086 , $w R$ (on $|F|^{2}$ ) $=0.171$ and goodness of fit $=1.047$ for all observed reflections. Number of refined parameters was 486. Max shift/ esd $=0.00$, mean shift/esd $=0.00$. Max and min peaks in final difference syntheses were 0.282 and -0.270 e $\AA^{-3}$, respectively.

## Acknowledgements

Financial support from Dirección General de Investigación of Ministerio de Economía y Competitividad [project CTQ2011-22433 and fellowship to T.G. (FPI program)] is gratefully acknowledged. M.E.B. thanks the University of Córdoba (Argentina) for financial support. We also thank the Centres Científics $i$ Tecnològics of the University of Barcelona (CCiTUB) for NMR, MS and X-ray diffraction facilities, and Ms. P. Domènech from the Institut de Química Avançada de Catalunya (IQAC, CSIC, Barcelona, Spain) for carrying out the elemental analyses.
