(Dated: November 21, 2016)

In this paper, we study gauged solutions associated to a massive vector field representing a spin-one condensate, namely the Proca field. We focus on regular spherically-symmetric solutions which we construct either using a self-interaction potential or general relativity in order to glue the solutions together. We start generating non-gravitating solutions, so-called, Proca Q-balls and charged Proca Q-balls. Then, we turn-on backreaction on the metric, allowing gravity to hold together the Proca condensate, to study the so-called Proca stars, charged Proca stars, Proca Q-stars and charged Proca Q-stars.

I. INTRODUCTION

Boson stars are gravitationally bounded macroscopic states made up of bosons. Firstly introduced in \cite{7, 8} as spherically symmetric solutions of the Einstein-Klein-Gordon equations, they remain being objects of study until present. Of particular interest are their possible astrophysical applications running from black-hole mimickers \cite{39–42}, black hole hair and clouds \cite{27–33} to dark matter candidates \cite{12}. Being simple tractable objects, they serve also as toy models helpful to understand the interplay between Field Theory, General Relativity and its possible extensions \cite{18}.

In order to construct boson stars, a fundamental aspect to be considered is the existence of an internal $U(1)$ symmetry, which will introduce an associated conserved charge that may give rise to classical solutions with non-zero total charge. Thus, a natural step forward is to gauge the global $U(1)$ symmetry. This was first done in \cite{9}, giving birth to the so-called charged boson stars.

An important family of classical objects was introduced in \cite{1}, where regular solutions for the non-gravitating Klein-Gordon equation of motion were found, known as Q-balls. These objects also rely on the existence of a conserved charge and can be obtained through the minimization of their corresponding free energy. Since gravity does not glue these solutions together, the parameters of their self-interaction potentials must have the right values in order to achieve actual solutions. Some interesting general properties were presented in \cite{4, 5}. Gauged extensions to these particular class were presented in \cite{2}.

When coupled to gravity, Q-balls become Q-stars \cite{10, 11}. Several other potentials, that would not give regular spherical solutions if not coupled to gravity, but of theoretical importance in other field theoretical contexts, were also studied under this framework \cite{13–17}.

Recently, new models of boson stars and Q-balls were presented in \cite{6, 21}. In these works, a vector field representing a spin-one condensate is studied, namely the Proca field. Hence, those particular solutions are the Proca stars and Proca-balls, respectively. In this paper, we study gauged extensions to these models, so-called charged Proca-balls and stars. For completeness we also consider self-interacting gauged and non-gauged gravitating solutions, which we shall call Proca Q-stars.

Real vector solutions were also studied in the literature \cite{24, 25} in the context of dark matter cores and accretion in compact objects. Without an internal symmetry this solutions can not be static and correspond to the vector equivalent of the scalar oscillantons introduced in \cite{26}.

The paper organizes as follows: in Section II we present our general model, in Section III we study non-gravitating solutions, i.e. Proca Q-balls and charged Proca Q-balls and, in Section IV we turn-on backreaction on the metric, allowing gravity to glue together the Proca condensate, giving rise to solutions named: Proca stars, charged Proca stars, Proca Q-stars and charged Proca Q-stars. Finally, in Section V we summarize our results and elucidate some possible future directions.

II. THE MODEL

By means of introducing a vector field representing a spin-one condensate, namely the Proca field, we arrive to the Maxwell-Einstein-Proca model, whose action reads

\[ S = \int d^4x \sqrt{-g} \left( R - \frac{1}{2} B^\mu \nabla \beta B^\mu \beta - U (B^\mu B_\mu) - \frac{1}{4} F^\mu \nu F_{\mu \nu} \right), \]  

(1)

where \( F^\mu \nu = \nabla^\mu A^\nu - \nabla^\nu A^\mu \) is the \( U(1) \) gauge-field strength and \( B^\mu = D^\mu B_\mu = D_\mu B^\mu \) with \( D_\mu = \nabla_\mu - iq A_\mu \). A similar lagrangian with negative cosmological constant was recently studied in [22, 23] in the context of AdS/CFT duality as a model for holographic p-wave superfluids \(^1\).

Varying the action introduced above (1) we derive the following equations of motion

\[ D^\nu B^\nu_\mu - U' (B^\mu B_\mu) = 0, \]  

(2)  

\[ \nabla^\nu F^\nu_\mu - iq (B^\nu B^\nu_\mu - B^\nu B^\mu_\nu) = 0, \]  

(3)  

\[ R^\mu \nu - \frac{1}{2} R g^\mu \nu = T^{(B)}_{\mu \nu} + T^{(F)}_{\mu \nu}, \]  

(4)

where \( R^\mu \nu \) is the Ricci tensor and \( T_{\mu \nu} \) the energy-momentum tensor of the matter fields.

The energy-momentum tensor has two different components. The first one, associated to the Proca field reads

\[ T^{(B)}_{\mu \nu} = -B^\mu \dot{\beta}^\nu - \ddot{B}^\mu \beta^\nu + \frac{1}{2} g^\mu \nu B^\sigma \beta^\sigma \beta^\lambda - U' (B^\mu B_\mu) (B_\mu \dot{B}^\nu + \dot{B}_\mu B^\nu) + U (B^\mu B_\mu) g^\mu \nu. \]  

(5)

while, the second one, associated to the Maxwell field is

\[ T^{(F)}_{\mu \nu} = -F^\mu \nu F^\nu_\mu + \frac{1}{2} g^\mu \nu F^\sigma \beta^\sigma \beta^\lambda. \]  

(6)

Since the model is invariant under \( U(1) \), a Noether current associated to this symmetry arises. This current is defined by

\[ j^\mu = \frac{1}{2} (B^\mu \beta^\nu - B^\mu \beta^\nu) . \]  

(7)

III. CHARGED PROCA BALLS

In this section we study non-gravitationally bounded solutions commonly named as “balls” \(^1\) in the literature. For this purpose, we consider a fixed Minkowski metric associated to a background flat space given by

\[ ds^2 = -dt^2 + dr^2 + r^2 d\Omega_2^2. \]  

(8)

In order to achieve actual solutions for these non-topological solitons, a self-interacting potential \( U \) is needed, which we defined

\[ U (B^\mu B_\mu) = m^2 \dot{B}^\mu B_\mu + \frac{\lambda}{2} (\dot{B}^\mu B_\mu)^2 + \frac{\hbar}{3} (\dot{B}^\mu B_\mu)^3. \]  

(9)

Here, \( m \) is the mass of the boson, while \( \lambda \) and \( \hbar \) are coupling constants. The simplest spherically-symmetric ansatz that admits non-trivial radial profiles reads

\[ B = e^{i\omega t} (u(r) + iv(r))dr; \quad A = A_t (r) dt. \]  

(10)

\(^1\) A non-minimal coupling term \( iq\gamma B^\mu \beta^\nu F^\mu \nu \) characterizing the magnetic moment of the vector field could be an interesting extension to this model (see, for instance, [23, 32]).
In this case, the equations of motion reduce to
\[
\begin{align*}
    u'' - (\omega + qA_t) \left( \frac{2}{r} v + v' \right) + \frac{2}{r} u' - hu^5 + (g + 2hv^2) u^3 - (m^2 + gv^2 + hv^4) u - qvA_t &= 0, \\
(-m^2 + \omega^2 + qA_t (2\omega + qA_t)) v + \left( (u^2 - \omega^2) (g - h (u^2 - \omega^2)) \right) v - (\omega + qA_t) u' &= 0, \\
A_t'' + \frac{2}{r} A_t' + 2qvu' - 2q (\omega + qA_t) v^2 &= 0.
\end{align*}
\]
(11)

Under these assumptions, it follows that near the origin the fields must behave as
\[
\begin{align*}
u(r) &\approx u(0) - \frac{1}{6} \left( \left( qA_t(0) + \omega \right)^2 + g\omega(0)^2 - h\omega(0)^4 - m^2 \right) u(0)^2 + O(r^4), \\
v(r) &\approx -\frac{1}{3} \left( qA_t(0) + \omega \right) u(0) r + O(r^3),
\end{align*}
\]
(12)

Then, in order to shoot to the desired asymptotic behavior at a fixed \(\omega\), we can use the free parameters \(u(0), A_t(0)\) at the origin, naturally setting the constraint \(\omega^2 < m^2\), as the asymptotic behavior reads
\[
u(r) \to c_\infty e^{-\sqrt{m^2 - \omega r}}, \quad v(r) \to \frac{c_\infty \omega}{\sqrt{m^2 - \omega^2}} e^{-\sqrt{m^2 - \omega r}}, \quad A_t(r) \to \frac{A_\infty}{r}.
\]
(13)

To ensure that the trivial solution is an absolute minimum of the energy \(E = \int d^3x \sqrt{-g} \epsilon = \int d^3x \sqrt{-g} T^{0}_{0}\), the potential parameters must satisfy the relation
\[
h > \frac{\lambda^2}{4m^2}.
\]
(14)

We are interested in solutions with a fixed value of the Noether charge \(Q = \int d^3x \sqrt{-g} \rho = \int d^3x \sqrt{-g} j^0\), where the non-topological solitons are the extrema of the \(F = E - \omega Q\) functional.

**Results**

Considering \(m^2 = -\lambda = h = 1\) for the numerics, we found solutions with charges up to \(q_{\max} = 0.03\). On Figure 1 we show the field profiles obtained for two such typical cases: \(q = 0\) and \(q = 0.02\).

![Figure 1: profiles for the uncharged (left panel) and charged (right panel, \(q = 0.02\)) solutions for \(\omega = 0.980\).](image)

Writing explicitly the charge and energy density, we obtain
\[
\begin{align*}
    \epsilon &= u'^2 + \omega^2 v^2 - 2\omega u v' + m^2 (u^2 + v^2) + \frac{\lambda}{2} (-3u^4 + 2u^2v^2 + v^4) + \frac{h}{3} (u^2 - \omega^2)^2 (5u^2 + v^2) + \frac{1}{2} A_t^2, \\
    \rho &= 2 (\omega + qA_t) v^2 - vu'.
\end{align*}
\]
(15) (16)
On Figure 2 we plot $\rho$ and $\epsilon$ profiles for the same cases described above.

On the other hand, the dependences of $E$ and $Q$ are presented on Figure 3 as functions of the soliton frequency. On this Figure we present all the range for $\omega$ that we managed to reach by means of our numerical code. There are two particular limits at which the energy and the Noether charge tend to infinity. These limits correspond to the so-called thin-wall regime (when $\omega \to \omega_{\text{min}}$) and the thick-wall regime (when $\omega \to 1$). We found $\omega_{\text{min}} \approx 0.915$ for $q = 0$ and $\omega_{\text{min}} \approx 0.953$ for $q = 0.02$.

As the soliton solutions could still decay into free bosons, it follows that an important magnitude to be analyzed is the energy difference between these two solutions, i.e. $E - mQ$. The $Q$ dependence of this magnitude is shown in the right panel of Figure 3. The curve obtained for $E - mQ$ consists of two branches, developing a spike at the junction point, where the energy and the Noether charge of the soliton attain their minimum values. This happens at $\omega \approx 0.980$ for $q = 0$ and $\omega \approx 0.985$ for $q = 0.02$. Roughly speaking, the plot shows that both charged and uncharged solitons are unstable to the decay in the free bosons in the thick-wall regime meanwhile stable to this decay in the thin-wall regime.

Figure 2: Charge (left panel) and Energy (right panel) density profile for the charged ($q = 0.02$, red) and uncharged (blue) solutions for $\omega = 0.980$.

Figure 3: Left panel: energy as a function of the frequency for uncharged solutions with $q = 0$ (blue) and charged solutions with $q = 0.02$ (red). The total charge follows closely the energy curve. Right panel: difference between the energies corresponding to the soliton and the free-boson solution as a function of the total charge (for $m = 1$). While both solitons are unstable to the decay of the free bosons in the thick-wall regime, they remain stable to this decay in the opposite thin-wall regime.

IV. PROCA STARS

In this section we focus on the study of spherically-symmetric static stars. We analyze four different types of stars, depending on the choice of the values of the lagrangian parameters, that we name as follows:
• Proca stars (PS): this model was introduced in [21] and corresponds to $q = 0, m^2 \neq 0, \lambda = 0, h = 0$. In particular, we fix $m^2 = 1$.

• Charged Proca stars (CPS): for which we gauge the $U(1)$ symmetry of the Proca stars by setting $q \neq 0$. This is equivalent to the gauged scalar case studied in [9] with respect to the non-gauged works [7, 8]. Just as in the scalar case, the maximum charge is $q^2 = \frac{1}{2}$. In particular, we take $q = 0.5, m^2 = 1, \lambda = 0, h = 0$.

• Self-interacting Proca stars (IPS): these solutions are gravitationally bounded solutions of Proca balls, introduced in [6] and reviewed in Section III when setting $q = 0$. We will also call them Proca Q-stars since they are the Proca version of Q-stars [10]. In this case, for the numerics, we consider $m^2 = -\lambda = h = 1$.

• Charged self-interacting Proca stars or charged Proca Q-stars (CIPS): the gauged version of the solutions described in the previous item. Their scalar version was studied in [11]. Again, for the numerics, we assume $m^2 = -\lambda = h = 1, q = \frac{1}{2}$.

For the gravitationally bounded solution, we start by assuming an ansatz for the metric

$$ds^2 = -\sigma^2(r)N(r)dt^2 + \frac{1}{N(r)}dr^2 + r^2d\Omega_2^2.$$  

(17)

As in the “balls” case studied in the previous Section, we consider the ansatz [10] for the matter fields and the expression [9] for the potential.

In this case, the derived equations of motion read

$$\frac{d}{dr} \left( \frac{(u' - (\omega + qA_t) r^2)}{\sigma} \right) - \frac{r^2u}{N^3\sigma^5} \left( -hu^4 + (g + 2hNv^2) N u^2 \sigma^2 - (m^2 + (g + hNv^2) N^2 \sigma^4) \right) = 0,$$

$$(\omega + qA_t) u' + (m^2 + (g + hNv^2) N \sigma^2 \sigma^2 v - (\omega + qA_t)^2 v - \frac{1}{N\sigma^2} \left( -hu^4 + (g + 2hNv^2) \sigma^2 N^2 u^2 v \right) = 0,$$

$$A'_t + \left( \frac{2}{r} - \frac{\sigma'}{\sigma} \right) A'_t + 2q v u' - 2q (\omega + qA_t) v^2 = 0,$$

$$(w + \frac{1}{2}grN^2v^4 + \frac{1}{3}hrN^2v^6 + rA_t^2 + \frac{ru^2}{\sigma^2} + \frac{rv}{\sigma} \left( (\omega + qA_t)^2 + m^2 \sigma^2 v - 2(\omega + qA_t) u' \right) +$$

$$+ \frac{rv^2}{6N^3\sigma^5} (10u^4 - 9(g + 2hNv^2) N u^2 \sigma^2) + \frac{ru^2}{N\sigma^2} \left( m^2 + (g + hNv^2) N^2 \sigma^2 \right) = 0,$$

$$\frac{\sigma'}{\sigma} + \frac{r}{2N\sigma^2} \left( \frac{1}{2} A_t^2 + \frac{\sigma^2 N'}{r} \right) + \frac{N - 1}{2rN} + \frac{r}{2N\sigma^2} (u' - (\omega + qA_t)^2 + \frac{1}{2} m^2 r \left( -v^2 - \frac{u^2}{N^2\sigma^2} \right) +$$

$$+ \frac{gr}{4N^3\sigma^5} (u^4 + 2N^2u^2v^2\sigma^2 - 3N^4v^4\sigma^4) - \frac{gr}{6N^4\sigma^6} (u^2 - N^2\sigma^2)^2 (u^2 + 5N^2v^2\sigma^2) = 0.$$  

Near the origin, the solutions must behave as

$$u \approx u_c - \frac{u_c}{6\sigma_c} \left( -hu^4_c + \sigma_c \left( -u^2_\sigma^2 + \lambda u_c^2 + (\omega + qA_{tc})^2 \right) \right) r^2 + O(r^4),$$

$$v \approx -\frac{u_c}{3\sigma_c^2} \left( \omega + qA_{tc} \right) r^2 + O(r^3),$$

$$\sigma \approx \sigma_c + \frac{1}{2\sigma_c^2} \left( m^2 \sigma^2 u_c^2 - \sigma_c^2 \lambda u_c^4 + hu_c^6 \right) r^2 + O(r^4),$$

$$N \approx 1 - \frac{1}{18\sigma_c^6} \left( 6m^2 \sigma^2 u_c^2 - 9\sigma_c^2 \lambda u_c^4 + 10hu_c^6 \right) r^2 + O(r^4),$$

$$A_t \approx A_{tc} + \frac{gu_c^2}{90\sigma_c^6} \left( m^2 \sigma^2 - \lambda \sigma_c^2 u_c^2 + hu_c^4 \right) (\omega + qA_{tc}) r^4 + O(r^6).$$

Here we have three free parameters $u_c, \sigma_c, A_{tc}$ which we shall use to shoot into the proper behaviors at infinity: that is, regularity for the matter fields $u, v$ and the gauge field $A_t$; and asymptotic flatness $\sigma(r \rightarrow \infty) \rightarrow 1$.

**Results**

Considering the values of $m, q, \lambda, \text{and} h$ described above for the numerics, we found different sets of stars. On Figure we show the field profiles obtained for two typical cases: an interacting Proca star with $\omega = 0.876$ and a charged Proca star with $\omega = 0.926$. Later, on Figure we plot $\rho$ and $\epsilon$ profiles for the same cases.
On the left panel of Figure 6 we plot the ADM masses $M$ and Noether charges $Q$ obtained for a whole set of uncharged ($q = 0$) and charged ($q = 0.5$) Proca stars considering field frequencies in the $\omega \sim 0.80 - 1.0$ range. For all cases, as $\omega \to 1$, both $M$ and $Q$ of the solutions vanish, while $Q/M \to 1$. In this limit, Proca stars become large and light, with very low mean densities, resulting trivial at $\omega = 1$. On the opposite, for smaller $\omega$, Proca stars get more compact. Both in the uncharged and charged cases, $M$ and $Q$ follow a spiral, towards different central configurations regarding the choice of $q$. For $q = 0$, this critical configuration is located around $\omega \approx 0.89$ [21], while for $q > 0$ this critical value becomes larger. Moreover, while for $q = 0$, the maximum of both $M$ and $Q$ occurs at $\omega_{\text{max}} \approx 0.875$, with $M_{\text{max}} < Q_{\text{max}} \approx 1$, for $q > 0$ all the critical values increase. Regarding the stability of these solutions, in the lower part of the spirals $M > Q$, and thus the binding energy $E = 1 - M/Q$ becomes negative, making all these regions unstable against perturbations [21]. An analogue behaviour is found for the self-interacting cases, which follow similar trends in all cases, as can be seen on the right panel of Figure 6.

Finally, on the left panel of Figure 7 we show the total ADM mass $M$ as function of the central density $u(0)$ for the four cases considered in this Section: (un)charged Proca stars and (un)charged self-interacting Proca stars. On the right panel of Figure 7 we plot the mass-radius profiles of the same solutions. In order to do so, we define the radio of the Proca star as [9]

$$R = \int d^3x \sqrt{-g} r f^0$$  \hspace{1cm} (20)

While uncharged and charged versions of both Proca and self-interacting stars show very similar trends in the mass-radius diagrams for the same parameters, they show a very different dependence on the central density, as the left panel of Figure 7.
evidences. In both families, the gauged-stars versions are more massive and less compact than the uncharged ones.

We worked in natural units but also setting $m = 1$. In order to recover physical units a physical value for the particle mass must be assumed. In Table I we show maximum masses and minimum radii for a canonical case. Note that both the mass and the radius are measured in units of $[M_{pl}^2/m]$ where $M_{pl}$ is the Planck mass. Then the compactness $\eta = \frac{2M}{R}$ is independent of the particle mass (for each of the families considered). For our solutions we find $\eta_{\text{max}} = 0.30$ (PS), 0.32 (IPS), 0.24 (CPS), 0.23 (CIPS) which are of course less than the Schwarzschild black hole value $\eta = 1$.

Table I: Maximum masses and minimum radii for the different solutions expressed firstly in dimensionless units (for $m = 1$) and then in physical units of solar masses $[M_\odot]$ and kilometers [km] for $m = 10^{-10}$ eV.

V. CONCLUSIONS

We have studied a broad class of spherically symmetric regular solutions involving a complex massive vector.

Firstly, we studied Proca-Q-balls, that is, non-gravitating solutions with a self-interaction potential which acts to hold the system together. We found both charged and uncharged solutions of this particular class of Q-balls below a critical charge depending on the choice of the free parameters available. For both charged and uncharged cases we found that solutions are only allowed in a limited range of frequencies $\omega_{\text{min}} < \omega < m$, with divergent energy in both minimum and maximum frequencies. This extrema define the so called thin-wall ($\omega \to \omega_{\text{min}}$) and thick-wall ($\omega \to m$) regimes. Moreover, analyzing in detail the $E - mQ$ relation, we conclude that in the thick wall regime the solutions are unstable and will decay into free “procons” or free Proca states.

Secondly, we also studied Proca-stars and Proca-Q-stars, that is, self-gravitating solutions. In this part, we extended the results of [21] for a broader class of potentials showing that self-gravitating solutions are indeed robust. In this sense, since it is reasonable to assume that dark matter in the Universe could be composed of different kinds of fundamental entities, condensates as vector Proca-stars studied here, as scalar Boson stars analyzed elsewhere, represent another viable dark component.

Looking forward, next steps for this study could come from extending our spherically symmetric to allow for rotation, in order to investigate spinning Proca-Q-balls, which could be done by considering a vector version of spinning non-topological solitons made of scalar fields [34][37]. In the same direction, it would also be interesting to find solutions where these fields act like a Kerr black hole hair or clouds following the steps of [27–31, 33]. On the other hand, clouds may also exist surrounding static black holes [32]. Extending the solutions found in this paper for our self-interacting model would then be a promising future approach to this field too.
