Hydrolytic enzymes production by Aspergillus section Nigri in presence of butylated hydroxyanisole and propyl paraben on peanut meal extract agar

Carla L. Barberis, María F. Landa, Mauricio G. Barberis, Guillermo Giaj-Merlera, Ana M. Dalcerò, Carina E. Magnoli

**ABSTRACT**

**Background:** In the last years, food grade antioxidants are used safely as an alternative to traditional fungicides to control fungal growth in several food and agricultural products.

**Aims:** In this work, the effect of butylated hydroxyanisole (BHA) and propyl paraben (PP) on two hydrolytic enzyme activity (β-glucosidase and α-α-galactosidase) by Aspergillus section Nigri species under different water activity conditions (aw: 0.98, 0.95 and 0.93) and incubation time intervals (24, 48, 72 and 96 h) was evaluated on peanut-based medium.

**Methods:** The activity of two glycosidases, β-glucosidase and α-α-galactosidase, was assayed using as substrates 4-nitrophenyl-β-D-glucopyranoside and 4-nitrophenyl-α-D-galactopyranoside, respectively. The enzyme activity was determined by the increase in optical density at 405 nm caused by the liberation of p-nitrophenol by enzymatic hydrolysis of the substrate. Enzyme activity was expressed as micromoles of p-nitrophenol released per minute.

**Results:** The major inhibition in β-glucosidase activity of A. carbonarius and A. niger was found with 20 mmol l⁻¹ of BHA or PP at 0.98 and 0.95 aw, whereas for α-α-galactosidase activity a significant decrease in enzyme activity with respect to control was observed in A. carbonarius among 5 to 20 mmol l⁻¹ of BHA or PP in all conditions assayed. Regarding A. niger, the highest percentages of enzyme inhibition activity were found with 20 mmol l⁻¹ of BHA or PP at 0.98 aw and 96 h.

**Conclusions:** The results of this work provide information about the capacity of BHA and PP to inhibit in vitro conditions two of the most important hydrolytic enzymes produced by A. carbonarius and A. niger species.

**Producción de enzimas hidrolíticas por Aspergillus sección Nigri en presencia de butiánisol butilado y propilparaben en medio de cultivo de agar con extracto de cacahuete**

**RESUMEN**

**Antecedentes:** En los últimos años, para controlar el crecimiento fúngico, en lugar de los fungicidas tradicionales, tanto en la industria alimentaria como en los productos agropecuarios se utilizan antioxidantes como aditivos alimentarios bien tolerados y sin riesgos de efectos adversos.

**Objetivos:** En el presente estudio, en medio de cultivo con cacahuete, se evaluó el efecto de butiánisol butilado (BHA) y propilparaben (PP) sobre la actividad de 2 enzimas hidrolíticas (β-glucosidasa y α-α-galactosidasa) producidas por especies de Aspergillus sección Nigri, en función de diferentes valores de actividad de agua del sustrato (aw: 0.98, 0.95 y 0.93) y tiempos de incubación (24, 48, 72 y 96 h).

**Métodos:** La actividad de las 2 glucosidazas (β-glucosidasa y α-α-galactosidasa) se evaluó usando como sustrato 4-nitrofenol (β-D-glucopiranósido y 4-nitrofenol α-D-galactopiranósido, respectivamente). La actividad enzimática se determinó mediante el aumento de la densidad óptica a 405 nm provocado...
por la liberación de p-nitrofenol, resultado de la hidrólisis enzimática del sustrato. La actividad enzimática se expresó como micromoles de p-nitrofenol liberado por minuto.

**Resultados**: La mayor inhibición en la actividad de β-β-glicosidasa de Aspergillus carbonarius y A. niger se observó con 20 mmol L⁻¹ de BHA o PP a 0,98 y 0,85 oW, respectivamente. Comparado con el control, en A. carbonarius se detectó una disminución significativa de la actividad de β-β-glicosidasa con 5 a 20 mmol L⁻¹ de BHA o PP en todas las condiciones examinadas. Con respecto a A. niger, los porcentajes más elevados de inhibición enzimática se observaron con 20 mmol L⁻¹ de BHA o PP a 0,85 oW y un tiempo de incubación de 5 h.

**Conclusiones**: Los resultados del presente estudio proporcionan información sobre la capacidad de BHA y PP para inhibir las enzimas más importantes producidas por las especies A. carbonarius y A. niger. © 2012 Revista Iberoamericana de Micolología. Peanut (Arachis hypogaea) is an economically important seed in Argentina. Most of the production is exported to different regions of the world, including European Union countries, and the USA; the rest is consumed internally. Each year, an important percentage of the peanut total production is left outside the external market due to fungal contamination at the post-harvest stage and mycotoxin production. In previous works, aflatoxin and ochratoxin producer species belonging to Aspergillus sections Flavi and Nigri have been reported as the main toxigenic fungi associated with peanut grains in Argentina. In several studies Aspergillus carbonarius is reported as the main ochratoxin A (OTA) producer, followed by species belonging to Aspergillus niger aggregate in tropical and temperate countries. Ochratoxin A has been extensively informed in several agricultural commodities, among them cereals and oilseeds destined for human and animal consumption.

Many scientists worldwide have studied the optimal conditions of water activity (Ow) and temperature for growth and bio-synthesis of OTA by ochratoxinogenic species belonging to section Nigri. In previous works, Astoreca et al. evaluated the influence of ecophysiological factors on growth and OTA production by Aspergillus section Nigri Aspergillus species isolated from different substrates in Argentina. These authors observed that OTA concentration increased as Ow level increased, with no significant production from 0,85 to 0,91 Ow over a range of temperatures 15, 25 and 30°C; and optimum production occurred among 0,95 to 0,99 Ow and 25 or 30°C depending on the species considered.

Food grade antioxidants, e.g., butylated hydroxyanisole (BHA), butylated hydroxy toluene (BHT) and antimicrobial agents as propyl paraben (PP), are used safely as alternatives at traditional fungicides to control fungal growth in several food and agricultural products. These antioxidants and antimicrobial agents have showed capability to limit Fusarium species growth and fumonisins production on natural substrates. Passene et al. have also shown that these compounds have antifungal effects against Aspergillus section Flavi species on peanuts. In previous works, BHA and PP single and combined have demonstrated ability to control growth of Aspergillus section Nigri species, and to inhibit OTA accumulation on peanut-based media under determined Ow and temperature conditions.

Kinetic studies with Penicillium verrucosum have shown a close correlation between hydrolytic enzyme production and OTA production. Quantitative enzyme assays for specific hydrolytic enzymes produced by spoilage fungi, have been shown to be good early indicators of growth prior to visible molding. In addition, Aspergillus spp. produced large amounts of hydrolytic enzymes such as N-acetyl-β-β-glicosaminidase, β-β-glicosidase, α-β-galactosidase, phosphatases, fucosidas, peptidases, lipases, amylases and sulphatases. However, less information is available in relation to environmental factors such as water availability on hydrolytic enzyme production by toxigenic fungi during colonization of grains.

Previous studies have demonstrated that BHA and PP increase the lag-phase length before growth of Aspergillus section Nigri species on peanut based media and peanut kernels when Ow and temperature decreased. However, no studies are available about the effects of phenolic antioxidants and antimicrobials on key hydrolytic enzymes produced during the early stages of infection by Aspergillus section Nigri species on cereals and oilseeds.

The aim of the present study was to continue the evaluation of the effect of antioxidant butylated hydroxyanisole and the antimicrobial propyl paraben now on the activity of two of the most important hydrolytic enzymes (β-β-glicosidase and α-β-galactosidase) produced by Aspergillus section Nigri species during the initial phases of growth, under different water activity conditions on peanut meal extract agar.

**Materials and methods**

**Fungal strains and identification**

Two Aspergillus section Nigri species, A. carbonarius (strain RCPG) and A. niger (strain RCP42), isolated from Argentinean peanuts, were used in this study. The morphology of these strains was examined according to Samson et al. The OTA production by RCPG and RCP42 on YES medium (yeast extract sucrose agar) and on peanut meal extract agar has previously been reported; and these strains were representative of the ones tested previously.

A PCR-based method was used to analyze DNA of A. carbonarius and A. niger to confirm the morphological identification. Two pairs of primers (CARBO1/2 and NIG1/2) designed from the calmodulin gene, produced PCR products of 371 and 245 bp for A. carbonarius and A. niger strains, respectively. The primers sequences read as follows: CARBO1: ACAAGCTTACAGTCCACAGAATAC CARBO2: TCTGCGCAGATTGTATCCCGTT; NIG1: GATTTCGACAGATTGTCCAGAA and NIG2: AAAGCCTTACAATCAGACAGCC. The amplifications were performed using the Termocycler MJ Research PTC-200 (MJ Research Inc., Watertown, MA) with the following cycling parameters: CARBO1: 94°C for 5 min, followed by 35 cycles of 50s at 94°C, 50s at 58°C and 1 min at 72°C with final extension for 7 min. NIG1: 94°C for 5 min, followed by 30 cycles of 50s at 94°C, 50s at 60°C and 1 min at 72°C with final extension for 7 min.

The strains are deposited in the culture collection of National University of Río Cuarto, Córdoba, Argentina (RC) (Aspergillus carbonarius RCPG, Aspergillus niger RCP42).

**Culture medium**

Peanut meal extract agar was prepared at 3% (w/v). Thirty grams of ground peanut per liter were boiled for 45 min and the resultant mixture filtered through a double layer of muslin. The volume was made up to 11 and agar-agar at 2% (w/v) was added. The water
activity of the basic medium was adjusted to 0.98, 0.95 and 0.93 with known amounts of glycerol. The basic medium was autoclaved at 120°C for 20 min before cooling it at 50°C and poured into 90-mm sterile Petri dishes. Water activity of representative samples of each treatment was checked at the beginning of the experiment with an AquaLab Series 3 (Decagon Devices, Inc., WA, USA).

Antioxidant and antimicrobial agent

The antioxidant 2,3,5,6-tetrahydroxypyridine (BHA) and antimicrobial agent n-propyl 4-hydroxybenzoate (PP) were used and obtained from Sigma–Aldrich Chemical (Dorset, UK). Stock solutions of BHA and PP (1mM) were prepared by dissolving 18 g in 100 ml of 95% ethyl alcohol-water mixture (v/v). The antioxidant and antimicrobial agent were added to the basic medium at 50°C to obtain the required concentrations (1, 5, 10 and 20 mmol l⁻¹ of medium).

Inoculation and incubation conditions

Petri dishes with peanut meal extract agar and each antioxidant or antimicrobial treatments were inoculated with 200 μl of spore suspension (1 × 10⁶ spores ml⁻¹) from a 7-day-old culture on 2% malt extract agar (MEA) of each strain and spread-plate over the surface using a surface-sterilized bent Pasteur pipette. Inoculated Petri dishes of the same α values were sealed in polyethylene bags. Twelve replicate plates per treatment were used and incubated at 25°C for 24, 48, 72 and 96 h; all the experiments were repeated twice. Twelve plates with peanut meal extract agar, without antioxidant or antimicrobial agent and conditioned at different levels of α values were used as controls at each sampling time.

Extraction of enzymes from basic medium

Using a cork borer, three discs of agar (each 6 mm diameter) were removed from both treatments and control plates at 24, 48, 72 and 96 h, and placed in 4 ml potassium extraction buffer (10 mmol l⁻¹, pH 7.2) for enzyme extraction. The glass bottles were shaken on a wrist-action shaker for 1 h at 4°C. The washings were decanted into 1 ml plastic microtubes and centrifuged in a bench microcentrifuge for 15 min at 450 × g at 4°C. The supernatant was removed and stored at −20°C until total enzyme activity determination. The completed assay was carried out twice.

Enzyme activity determination

The activity of two glycosidases, β-D-glucosidase and α-D-galactosidase, was assayed using as substrates 4-nitrophenyl-β-D-glucopyranoside (4.0 mmol l⁻¹) and 4-nitrophenyl-α-D-galactopyranoside (2.0 mmol l⁻¹), respectively (Sigma–Aldrich). Enzyme extract (40 μl), substrate solution (40 μl) and 25 mmol l⁻¹ of acetate buffer (20 μl) were placed in the wells of the microtitre plate along with the appropriate controls and incubated for 1 h at 37°C. The reaction was stopped by the addition of 1 M Na₂CO₃ solution (5 μl). The enzyme activity was measured using a MXR multispectrometer plate reader (Dynex Technologies Ltd., Hillinghurst, UK), by the increase in optical density at 405 nm caused by the liberation of p-nitrophenol by enzymatic hydrolysis of the substrate. Enzyme activity was calculated from a calibration curve of absorbance against p-nitrophenol concentration and expressed as micromoles of p-nitrophenol released per minute.

Number of enzymatic activity analysis = 3 α values × 1 temperature × 2 species × 4 concentrations of 1 antioxidant and 1 antimicrobial × 4 incubation time × 3 replicates.

Statistical analysis

All assays were carried out in triplicates. Analysis of variance to evaluate the effect of antioxidant and antimicrobial treatments, α values, strain, and incubation time on total enzyme production was done. Effect of single, two and three-way interactions of treatments (α values × T, α values × C, T × C, α values × T × C) for enzyme production was done and the LSD test was performed to determine differences between pairs of treatments. The analysis was conducted using PROC GLM in SAS (SAS Institute, Cary, NC).

Results

This study investigated whether BHA and PP may inhibit the two most important hydrolytic enzymes production by Aspergillus section Nigri species growing on peanut-based medium under different water availability conditions. In general, in control treatments (plates without antioxidant or antimicrobial agent), A. carbonarius produced more β-D-glucosidase than α-D-galactosidase at all incubation time, being the maximum production at 0.98 α values and 96 h, whereas in A. niger no differences were observed in β-D-glucosidase and α-D-galactosidase production, being the maximum production at 0.95 α values and 96 h (P < 0.0001) (Tables 1 and 2).

Table 1 compares the effect of different levels of food grade antioxidant BHA and antimicrobial agent PP, α values and incubation time on the β-D-glucosidase total activity for A. carbonarius and A. niger. For A. carbonarius, in general, from 5 mmol l⁻¹ of BHA and PP, a significant reduction on enzyme activity with respect to control was observed in all conditions assessed, except at 0.98 α values and 24 h, whereas at 20 mmol l⁻¹ of BHA or PP and 0.98 α values the maximum reduction in enzyme activity was observed (P < 0.0001). The β-D-glucosidase activity of A. niger was reduced when the concentration of BHA or PP was increased (P < 0.0001). The highest percentages of enzyme inhibition activity were observed with 20 mmol l⁻¹ at 0.95 α values and 96 h.

Table 2 shows the temporal changes in α-D-galactosidase activity of A. carbonarius and A. niger at different levels of BHA and PP, α values and incubation time. For A. carbonarius, among 5–20 mmol l⁻¹ of BHA or PP, a significant decrease in enzyme activity with respect to control was observed for both species in all conditions assessed. The highest percentage of enzyme inhibition was found at 20 mmol l⁻¹ of BHA and PP, 0.98 α values and 72 h of incubation (P < 0.0001). In addition, this behavior was also observed at 0.95 α values at the same antioxidant and antimicrobial agent concentration and incubation time. Regarding A. niger, in general, the activity of this enzyme diminished as BHA or PP concentration increased. The significant inhibition was observed from 1 mmol l⁻¹ of BHA or PP at 0.98 and 0.95 α values (P < 0.0001). The highest percentages of enzyme inhibition activity were found with 20 mmol l⁻¹ of BHA or PP at 0.95 α values and 96 h.

A significant stimulation in β-D-glucosidase activity of A. carbonarius with respect to control was observed in treatment with 1 mmol l⁻¹ of BHA at 0.93 α values and 96 h. The same behavior was observed in A. niger species at major incubation time with 1 mmol l⁻¹ of BHA at 0.98 and 0.93 α values, and with 10 mmol l⁻¹ at 0.98 α values and 96 h, whereas for PP this behavior was observed at the same incubation time and 0.93 α values only with the lowest antimicrobial agent concentration (Table 1). Regarding enzymatic activity of α-D-galactosidase in A. carbonarius a significant stimulation was found from 1 to 5 mmol l⁻¹ of BHA, 1 mmol l⁻¹ of PP at 0.93 α values and 96 h (P < 0.0001), whereas in A. niger a significant stimulation was observed with 1 mmol l⁻¹ of PP at 0.98 α values and 96 h (P < 0.0001) (Table 2).

The analysis of variance of the data showed that for α-D-galactosidase and β-D-glucosidase total activity, single factors

Discussion

In control treatments the highest activities of α-D-galactosidase and β-D-glucosidase were found at 0.98 αw and 0.95 at 96 and 72 h for A. carbonarius and A. niger species, respectively. Similar results were previously informed by Marin et al., who evaluated the total and specific activities of α-D-galactosidase, β-D-glucosidase and N-acetyl-β-D-glucosaminidase of Fusarium verticillioides and F. proliferatum fungi on producing species. These authors reported that the activity of these enzymes was important during early germination, and maximum growth was produced at 0.98 αw with significantly less effect at 0.95 and 0.93 αw, being the exception the total activity of α-D-galactosidase, which was similar at both 0.95 and 0.93 αw. Likewise, other study (Alam et al.) showed that the total activity of esterase, lipase, acid phosphatase, β-glucosidase and N-acetyl-β-D-glucosaminidase of A. fumus increased as αw and time increased when this species developed on Czapek Yeast Extract Agar (CYA) medium.

The analysis of variance on the effect of single (time, αw and antioxidant treatments), two- and three-way interaction showed that all factors alone and all interactions were statistically significant (P<0.0001). These results agree with those obtained by Reynoso et al., who evaluated the effect of BHA, PP and butylated hydroxytoluene (THBP) alone or in combination, on lag phase, growth rate, hydrolytic enzyme activity and fumonisin production by F. verticillioides and F. proliferatum species on maize based medium. Contrary to what was observed in the present study, these authors found in the control assay the highest α-D-galactosidase, β-D-glucosidase and N-acetyl-β-D-glucosaminidase activity at 0.95 αw after 96 h. While all the antioxidant treatments (single or combined) produced a significant reduction in activity of these enzymes at all water availability assayed (0.95, 0.98 and 0.95) after 96 h, an increase in β-D-glucosidase activity of F. verticillioides was observed in the treatment with 10 mm THBP at all αw levels. In comparison with the present results, a significant stimulation in activity of β-D-glucosidase and α-D-galactosidase with respect to control in some treatments was observed. This stimulation was done at 96 h and depended on the antimicrobial or antioxidant concentration, the species and αw condition assayed. In A. carbonarius species this behavior was observed only at the lowest αw condition (0.95), with all BHA levels, 1 and 5 mmol l−1 of PP.

Mean values based on triplicate data. Mean in a row with a letter in common are not significantly different according to LSD test (P<0.0001).

In the present study a significant inhibition in enzyme activity was observed from 5 mmol l⁻¹ of BHA or PP. These results partially agree with those obtained in previous ecophysiological studies with these species, where the inhibition of growth and OTA production in vitro conditions becomes significant from 10 mmol l⁻¹ of BHA and 5 mmol l⁻¹ of PP. In agreement with the present study the stimulation of both fungal growth and OTA production was also found, but only at the lowest concentration assayed (1 mmol l⁻¹).

In another study on peanut kernels, Barbéris et al. showed that the stimulation in OTA production was found at different levels of BHA or PP (5 mmol g⁻¹ PP and 5 mmol g⁻¹ BHA at 18°C, and 5, 10, and 20 mmol g⁻¹ PP at 25°C).

The data presented show that different levels of BHA or PP are able to inhibit two of the most important hydrolytic enzymes produced by A. carbonarius and A. niger species at 0.98, 0.95 and 0.93 mm, and 25°C on peanut based medium. The effect of BHA or PP on the enzymes involved in early substrate colonization process suggests that the ochratoxinogenic strains could be maintained in lag phase for a period of time by the use of certain concentrations of BHA and PP, delaying the spoilage and OTA contamination of grains in the storage.

In conclusion, further assays need to be carried out to test the effectiveness of BHA in combination with BHA as inhibitors of hydrolytic enzyme activity and OTA production in ochratoxinogenic Aspergillus section Nigri species on natural peanut seeds. From a health point of view it is known that BHA and PP are considered as safe additives for food (GRAS) by the US Food and Drug Administration (FDA). Our finding further emphasizes the antifungal impact of these chemical products against storage fungi on grains and enhances the possibility to use them as an alternative to replace the traditional fungicides in controlling ochratoxinogenic Aspergillus species and OTA occurrence.
