Abstract

1 The aim of the present article is to review experimental evidence which suggest joint
2 involvement of both the dopaminergic and neurotensinergic systems in stress
3 conditions. At present, the concept of stress refers to an environmental demand
4 exceeding the normal regulatory ability of an organism, particularly during
5 unpredictable and uncontrollable situations. Chronic stress yields devastating effects
6 including cognitive and working memory dysfunctions, for which neurotransmission
7 mediated by the catecholamines dopamine and noradrenaline is crucial. Catecholamine
8 synthesis depends on the rate-limiting enzyme, tyrosine hydroxylase, whose expression
9 is associated with working memory and the response to chronic stress. Neurotensin is a
10 tridecapeptide widely distributed in the nervous system, at both central and peripheral
11 levels, which behaves as a neurotransmitter or neuromodulator. It mediates diverse
12 biological actions including reward, locomotion, pain modulation and stress.
13 Neurotensin and its high affinity NTS1 receptor are densely localized in areas that
14 process emotion (amygdala nucleus), cognition (such as hippocampal nuclei and
15 cortical areas) and the response to stress (hypothalamic nucleus). Experimental evidence
16 indicates a crosstalk between the dopaminergic and the neurotensinergic systems either
17 from an anatomical or a biochemical point of view. It is suggested that a concomitant
18 alteration of dopaminergic and neurotensinergic systems takes place in diverse stress
19 conditions.

18 **Basic concepts of stress**

19 The most recent revised concept of stress has been defined as “any
20 *environmental demand that exceeds the physiological regulatory capacity of an*
21 *organism*”[1], particularly “*during situations of unpredictability and uncontrollability*”
22 [2]. The major neuroendocrine and physiological stress response to a threat from a
23 dangerous situation that triggers the ‘fight-or-flight’ response is the activation of the
24 hypothalamic-pituitary-adrenal (HPA) axis. Activation of the HPA axis is triggered by
25 corticotrophin releasing factor in the paraventricular nucleus that induces
26 adrenocorticotrophic hormone (ACTH) release from the pituitary, which in turn releases
27 glucocorticoids from the adrenal. The end product of HPA axis activation (i.e. the
28 release of glucocorticoids by the adrenal gland) serves to alert an organism to
29 environmental and physiological changes and to maintain homeostasis [3]. However,
30 another core neuroendocrine response to stressful stimuli is the activation of the
31 autonomic nervous system, which results in a rapid release of noradrenaline in the brain,
32 by activation of locus cerulean neurons. The release of corticotrophin releasing factor as
33 neurotransmitter in the locus coeruleus leads to the activation of medullary centers,
34 which control the sympathetic nervous system. Sympathetic processes may stimulate a
35 neural pathway via ganglia, and an endocrine pathway that elicits the release of
36 catecholamines, epinephrine and norepinephrine, into the circulation by the adrenal
37 glands. Circulating catecholamines stimulate effector organs via specific adrenergic
38 receptors [4]. Nevertheless, it has nowadays become evident that the dopamine system
39 plays a key role in the response to stress, most especially in the pathological response
40 observed in many psychiatric disorders.

Dopaminergic system and stress

The catecholamine dopamine serves as a neurotransmitter in several important pathways in the CNS where it controls a variety of functions including locomotor activity, cognition, emotion, positive reinforcement, food intake, and endocrine regulation [5]. Neurons in the adult bilateral mesodiencephalic dopamine system (A8–A10) give rise to prominent forebrain projections and receive inputs from various other brain regions. Dopamine containing neurons can be divided into four main groups: nigrostriatal, mesolimbic, mesocortical and tuberohypophysial [6].

Dopamine is synthesized from the essential aminoacid tyrosine by the rate-limiting enzyme, tyrosine hydroxylase (TH), to form L-3, 4-dihydroxyphenylalanine (L-DOPA). L-DOPA is thereafter decarboxylated by aromatic L-amino acid decarboxylase to form dopamine [7]. All known physiological functions of dopamine are mediated by five subtypes termed D1 to D5 dopaminergic receptors. All are G-protein-coupled receptors (GPCRs) with seven hydrophobic domains, an extracellular N-terminus and an intracellular C terminus segment. Based on their property to couple to either $G_{\alpha s}$ proteins or $G_{\alpha i}$ proteins that stimulate or inhibit the production of the second messenger cAMP, respectively, dopamine receptors are classified as D1-class receptors (D1 and D5) or D2-class receptors (D2, D3 and D4) [8,9]. The D1 receptor is the most widespread dopamine receptor and is found in the nucleus accumbens, amygdala, caudate putamen and prefrontal cortex. D5 is mostly expressed in the frontal cortex, hippocampus and caudate putamen. The three D2 type receptors D2, D3 and D4 are primarily expressed in the nucleus accumbens, and olfactory tubercle. In addition, D2 is also expressed in caudate putamen, D3 in Island of Calleja and ventrotectal area, and D4 in hippocampus, caudate putamen and frontal cortex [5,10].

Several studies in the past decades, have convincingly demonstrated that DA plays a key role in the response to stress, and that the DA system is activated by maintained stressful stimuli [11]. Out of the four main pathways described, the mesolimbic system seems to be mainly implicated in this response since it is involved in the processing of natural and artificial rewards mediating the hedonic aspects of rewarding stimuli [12], acting as a learning signal for behavioural reinforcement [13], and involved in motivation and attention processes [14,15].

It is well known that chronic stress yields devastating effects including cognitive and working memory dysfunctions, for which transmission mediated by catecholamines

1 dopamine and noradrenaline in the prefrontal cortex is crucial. Since catecholamine
2 synthesis depends on the rate-limiting enzyme TH, this enzyme is thought to play an
3 important role in prefrontal cortex function. There is an association between tyrosine
4 hydroxylase expression in the prefrontal cortex and working memory, which produces
5 two distinct population of rats in terms of working memory capacity and response to
6 chronic stress [16].
7
8
9

10 Acute footshock stress leads to activation of TH in the locus coeruleus, pre-
11 synaptic terminals in the mPFC and adrenal medullary chromaffin cells, as well as
12 changes inactivity of the HPA axis [17]. On the other hand, acute immobilization
13 prevents locus coeruleus TH mRNA levels from rising significantly, while
14 glucocorticoids appear to decrease their capacity to restrain locus coeruleus TH mRNA
15 during repeated immobilization [18].
16
17
18
19
20

21 There seems to be links between catecholamines (norepinephrine and dopamine)
22 with corticotrophin-releasing factor and drug addiction. To illustrate, compulsive drug
23 use associated with dependence is mediated by loss of function of reward systems and
24 recruitment of key brain stress systems such as corticotrophin-releasing factor and
25 norepinephrine in the extended amygdala. It has been advanced that addiction processes
26 involve a profound activation of stress systems in the brain that interact but are
27 independent of hormonal stress systems [19]. The ability of drug of abuse to enhance
28 extracellular concentrations of dopamine in the nucleus accumbens seems to be a crucial
29 common denominator for the development of drug addiction [20] and corticotrophin-
30 releasing factor participates in stress-induced drug abuse [21].

41 Early life stress has also been largely studied in relation to the dopaminergic
42 neurotransmission. Restraint stress exerted onto the pregnant dam produces long lasting
43 effects on the dopaminergic development of the offspring. Accordingly, prenatal stress
44 increases dopamine D2 receptors in limbic areas, decreases dopamine stimulated release
45 in cortical areas whereas it increases in NAc, disrupts the dopamine-glutamate balance
46 and impairs the expression of specific TFs along development as well as the expression
47 of TH and transporters [22].

55 **Neurotensinergic system and stress**

56 Neurotensin is a tridecapeptide widely distributed in the nervous system, at both
57 central and peripheral levels. It can behave as a neurotransmitter or as a
58
59
60
61

64
65

1 neuromodulator, exerting diverse biological actions [23]. Neurotensin is involved in
2 various processes, such as reward, locomotion, pain modulation and stress.
3 Administration of neurotensin to the central nervous system produces a wide variety of
4 effects, including the regulation of the stress response [24,25].
5
6

7 Neurotensin actions are mediated by its binding to a group of receptors [26].
8 Two of them, denominated NTS1 and NTS2 receptors, bind neurotensin with high and
9 low affinity, respectively. Both belong to the seven transmembrane domain receptors
10 family coupled to G proteins. Another two neurotensin receptor types are mainly
11 localized intracellularly and are termed NTS3/sortilin and nts4/SorLA [27]. The diverse
12 functions of neurotensin at central nervous system have been reviewed [28].
13
14
15
16
17

18 Radioimmunoassays carried out in brain of a variety of species disclosed
19 neurotensin distribution. High levels of this peptide are found in hypothalamus and
20 basal forebrain, intermediate concentrations are found in basal ganglia, brainstem and
21 dorsal horn of the spinal cord whereas low levels are found in thalamus and cortex (see
22 [25,29]). Most interesting, neurotensin and NTS1 receptor are densely localized in areas
23 that process emotion (amygdala nucleus), the response to stress (hypothalamic nucleus)
24 and/or cognition (such as hippocampal nuclei and cortical areas) (see [30]).
25
26

29
30

31 Glucocorticoids and their receptors are present in most neuronal cells, in
32 accordance with their widespread actions on neuronal metabolism and are known to be
33 key elements in the stress situation. Steroid hormones released from peripheral
34 endocrine glands may directly regulate brain functions through specific brain areas.
35 These effects may be rapid or alternatively, involve long-term changes at the genomic
36 level (for references, see [31]). High densities of neurotensin terminals and neurotensin
37 binding are present in the parvocellular division of the paraventricular nucleus where
38 corticotrophin-releasing factor-producing neurons are present [32,33].
39
40
41
42
43
44
45

46 Intracerebroventricular administration of neurotensin enhances plasma levels of
47 adrenocorticotrophic hormone from anterior pituitary and corticosterone from adrenal
48 gland [33,34]. It has been suggested that endogenous neurotensin regulates HPA axis
49 activity in stress condition by increasing corticosterone plasma levels [33,35-38]. Data
50 from recent years have accumulated suggesting that neurotensin is physiologically
51 involved in the regulation of the HPA axis, modulating ACTH and corticosterone
52 release. Several studies including administration of neurotensin, lesion of the
53 hypothalamus and antagonist administration among others, illustrate this observation: a)
54 Central administration of neurotensin activates the HPA axis, an effect most likely
55

63
64
65

1 dependent upon the release of corticotrophin-releasing factor. Film and emulsion
2 autoradiography shows that ¹²⁵I-neurotensin labels hypothalamic nucleus, with
3 relatively high densities of neurotensin binding sites in the paraventricular nucleus. SR
4 48692 and its analogue 48450, antagonists for NTS1 receptor, compete for ¹²⁵I-
5 neurotensin binding. These findings indicate that the hypothalamus and the HPA axis
6 may be the anatomical substrate for neurotensin effects on neuroendocrine functions
7 (for references, see [33]). b) Bilateral lesions of the paraventricular nucleus of the
8 hypothalamus markedly reduces neurotensin stimulation of ACTH and corticosterone
9 release, indicating that the paraventricular nucleus is essential for neurotensin
10 stimulatory action [35]. During heat stress significant elevations in blood level of
11 corticosterone and ACTH, indicators of the HPA axis, are recorded. At the same time,
12 neurotensin increases in the hypothalamus but diminishes in the nucleus accumbens
13 [39]. c) HPA function was studied under basal conditions and during restraint stress
14 after central administration of NTS1 receptor antagonist SR 48692. Chronic
15 administration of this antagonist to the paraventricular nucleus of the hypothalamus
16 attenuates both diurnal and stress-induced enhancements in HPA activity. SR 48692
17 diminishes the diurnal enhancement in plasma ACTH and corticosterone during the
18 evening phase of the cycle whereas it fails to modify morning levels. Restraint-induced
19 enhancement in plasma ACTH and corticosterone levels are also reduced in SR 48692
20 treated animals. Results suggested that SR 48692 effects are restricted to periods of
21 stimulated HPA activity. A decrease in corticotrophin-releasing hormone-like
22 immunoreactivity is observed in the paraventricular nucleus following chronic SR
23 48692. Besides, a parallel decrease in corticotrophin-releasing hormone-like
24 immunoreactivity is recorded in the external area of the median eminence. Findings
25 suggest that endogenous neurotensin leads to the increase in HPA activity during
26 periods of enhanced stimulation (for references, see [36]). d) The secretion of ACTH
27 depends on hypophysiotrophic factors released from neurons of paraventricular nucleus
28 of the hypothalamus. Potential role of neurotensin in the regulation of the different
29 components of the HPA axis under basal and stress conditions have been investigated.
30 Implants of SR 48692 above the paraventricular nucleus reduce ACTH and
31 corticosterone plasma levels after tail cut procedure. Besides, exposure of animals to a
32 novel environment for 30 min reduces ACTH and corticosterone plasma levels in the
33 SR 48692 treated group. Chronic administration of SR 48692 reduces corticotrophin-
34 releasing factor mRNA in the parvocellular division of the paraventricular nucleus of

65

1 the hypothalamus. This treatment likewise enhances vasopressin and vasopressin
2 mRNA levels in the magnocellular neurons of the paraventricular nucleus whereas
3 oxytocin plasma levels are not affected. Findings suggest that endogenous neurotensin
4 in the paraventricular nucleus plays a tonic stimulatory role on HPA axis but an
5 inhibitory effect on vasopressin secretion (for references, see [35]).
6
7

8
9 It is known that stress activates neural systems that suppress pain sensation,
10 denominated stress-induced analgesia [40], in which neurotensin plays an important role
11 [27]. In fact, exogenous neurotensin produces pain inhibition regardless of the way of
12 administration or the analgesic test employed [41]. Stress-induced analgesia following
13 water avoidance or restraint stress is reduced in neurotensin-deficient mice. Moreover,
14 genetic and pharmacological approaches show that NTS2 receptors mediate this non-
15 opioid stress-induced analgesia. Accordingly, mice lacking NTS2 receptor exhibit
16 reduced stress-induced analgesia following cold water swim stress [38].
17
18

19 Reports on the effect of stress on the NT system, mostly depends on the type of
20 stress as much as the brain area studied. To offer some few examples, cold swim stress
21 exerts an increase of the NT mRNA in the lateral hypothalamus and the medial preoptic
22 area [42]. Cold water restraint decreases NT mRNA and levels of NT in Nucleus
23 accumbens, increases NTR binding sites and decreases NTR mRNA. [43], Whole-body
24 vibration stress exerts an increase of NT-like immunoreactivity in frontal cortex and
25 hypothalamus [44]. Evidence indicates that stress during postnatal development is
26 associated with enhanced risk for anxiety disorders, depression as well as substance
27 abuse later in life. Maternal separation enhances freezing behaviours in fear-conditioned
28 stress and decreases the gene expression of NTS1 receptor but not that of neurotensin or
29 NTS2 receptor in amygdala of adult rats (for references, see [30]).
30
31

32 Taken together these studies clearly demonstrate not only that the infliction of a
33 stress insult alters the neurotensinergic system but that neurotensin exerts a
34 physiological modulation of the HPA axis.
35
36

37 **Interactions between dopaminergic and neurotensinergic systems**

38 There is nowadays little doubt on the existing interaction between dopaminergic
39 and neurotensinergic systems both from an anatomical and a biochemical point of view
40 [45,46]. To illustrate the anatomical distribution, main areas and pathways for both
41 systems are shown in Figure 1. For a detailed background on the experimental evidence
42 supporting this interaction the reader is referred to excellent reviews on this subject

1 [25,47]. In brief, there are anatomical and functional interactions between neurotensin,
2 the mesotelencephalic dopamine system and structures innervated by dopaminergic
3 projections [46]. Experimental results come from several approaches, including the
4 study of neurotensin effects on the mesotelencephalic dopaminergic projections, the
5 action of dopamine on neurotensin levels in some brain areas (striatum, ventral
6 mesencephalon and limbic forebrain), the detection of neurotensin
7 (immunohistochemically) or that of neurotensin/neuromedin mRNA after dopamine
8 receptor blockade and stimulation at striatum (for original articles, see [25]).
9

10
11
12
13
14 Moreover, evidence obtained from biochemical binding, microdialysis,
15 electrophysiological and co-immunoprecipitation studies, as well as from biophysical
16 approaches, specially bioluminescence resonance energy transfer (BRET2) (see [47,48]
17 for references) has convincingly demonstrated the existence of an heteromer composed
18 by the NTS1 receptor and dopaminergic D2 receptor. Both receptors are GPCRs but
19 dopaminergic D2 receptor family exhibits a wide variety of signaling diversity which is
20 due to numerous factors, including the ability of receptors to adopt multiple active states
21 with particular effector-coupling profiles. Among this is the ability to form homo- or
22 heterodimers with proper signaling, pharmacology as well as receptor activation from
23 desensitization and internalization [49]. Allosteric mechanisms between these receptors
24 may be operative and selective antagonistic NTS1 receptor-D2 receptor interactions
25 enhance the diversity of dopamine signaling by decreasing dopaminergic D2 receptor-
26 mediated dopamine signaling over dopaminergic D1 receptor-mediated dopamine
27 signaling [50].

35
36
37
38
39

40 It is important to point out that the effects of neurotensin on the dopamine
41 system has the obvious potential implication in many diseases of the CNS traditionally
42 linked to dopamine such as stress, schizophrenia, psychostimulant drug abuse and
43 Parkinson among others [25,47,51]. It is of interest to remark that among all these
44 pathologies, particular attention should be considered in relation to drug abuse and
45 stress, as already pointed out [25].
46
47
48
49
50
51
52

53 **Concomitant alteration of dopaminergic and neurotensinergic systems** 54 **under stress condition** 55

56 As mentioned above many pathological conditions has been linked to stress and
57 a wealth of studies suggest a link between central DA systems and the HPA axis. Since
58
59
60
61
62
63
64
65

1 neurotensin system spreads consistently in the DAergic and HPA axis, it has been
2 suggested that neurotensin play a critical role in mediating the linkage.

3
4 The exposure to acute mild footshock produces a selective and regionally
5 specific enhancement in neurotensin-like immunoreactivity concentrations in the ventral
6 tegmental area. It should be recalled that this area is the source of the dopaminergic
7 innervation of the mesocortical and mesolimbic dopaminergic regions. Interestingly,
8 levels of dopamine metabolite, 3, 4-dihydroxyphenylacetic acid, increase only in the
9 ventral tegmental area and medial prefrontal cortex. These findings led to the suggestion
10 that neurotensin in the ventral tegmental area is involved in activation of certain
11 mesotelencephalic dopamine neurons [52].
12
13
14
15
16
17

18 The central amygdaloid nucleus is part of the amygdaloid body, known to
19 participate in several stress related situations. Immunocytochemical studies disclosed
20 that this area is densely innervated by nerve terminals containing factors potentially
21 involved in stress. Some of them are TH, corticotrophin releasing factor and
22 neurotensin. Immunoreactivity for corticotrophin releasing factor and neurotensin are
23 present in perikarya of numerous neurons in this area (for references, see [53]). Stress
24 stimulates the expression of the immediate early gene c-fos in parvocellular neurons of
25 the paraventricular nucleus, many of its neurons also contain corticotrophin-releasing
26 factor immunoreactivity [54]. Besides, after stress immobilization, colocalization of Fos
27 and glucocorticoid receptor-like immunoreactivities was shown in the amygdaloid
28 complex [50]. Immunocytochemical double staining disclosed colocalization of the Fos-
29 immunoreactive neurons with peptide and TH containing structures. Immobilization
30 stress enhances Fos, peptide and TH immunoreactive neurons. These results suggest
31 that stress increases the synaptic activity of the central amygdaloid nucleus, which
32 stimulates c-fos expression. In turn, Fos may regulate the expression of several peptide
33 genes, including those for neurotensin and corticotrophin releasing factor, thus affecting
34 the peptidergic efferent from the central amygdaloid nucleus (for references, see [53]).

49 Catecholamines and neurotensin in the central amygdaloid nucleus have been
50 implicated in the integration of the autonomic response to stress. The cellular substrate
51 for this integration was investigated with rat antiserum against neurotensin and rabbit
52 antiserum against catecholamine-synthesizing enzyme, TH. These studies led to the
53 ultrastructural localization and dual localization in the central amygdaloid nucleus by
54 peroxidase-antiperoxidase and immunoautoradiography methods. In single and dual
55 labeling assays, neurotensin-like immunoreactivity is detected in perikarya and
56

65

1 processes. In the dual labeling assay, perikarya contain only neurotensin-like
2 immunoreactivity while nerve endings contain TH and/or neurotensin-like
3 immunoreactivity. Findings indicate that in rat central amygdaloid nucleus two
4 populations of neurons differ regarding to the distribution of neurotensin, and that the
5 output from neurons containing neurotensin is modulated by direct input from nerve
6 endings containing neurotensin and/or catecholamines [55]. The release of neurotensin
7 and catecholamines (most likely dopamine), from the same or from distinct nerve
8 terminals on common targets in the central amygdaloid nucleus may explain certain
9 similarities in the functions of these neuroactive substances related to stress [55].

There is evidence indicating that neurotensin modulates selectively the dopamine mesolimbic system when compared with the mesocortical pathway. Daily i.p. administration of SR 48692 to rats for 15 days leads to the increase in the expression of tyrosine hydroxylase mRNA and protein in the ventral mesencephalon. Simultaneous *in vivo* microdialysis in the nucleus accumbens shell and the medial prefrontal cortex discloses that neurotensin receptor blockade for 15 days decreases basal dopamine extracellular levels and its metabolites in the nucleus accumbens shell whereas dopamine levels in the medial prefrontal cortex remain unchanged. In animals subjected to a forced swimming stress, which enhances extracellular dopamine levels in the medial prefrontal cortex, administration of SR 48692 fails to modify the stress-induced enhancement in dopamine.

Another interesting result is related to the modulation of mesencephalic dopamine neurons by glucocorticoids. The repeated treatment with the neurotensin receptor antagonist fails to modify basal levels of free corticosterone but reduces the increase induced by forced swimming stress [37]. These findings suggest the involvement of NTS1 receptor in the modulation of mesencephalic dopamine neurons in the stress behaviour.

The human neuroblastoma cell line CHP212 expresses functional high affinity NTS1. The exposure of these cells to JMV 449, a stable neurotensin agonist, increases TH protein and mRNA. JMV 449 effect occurs by an increase in the transcriptional activity of the TH gene. These findings indicate that modulation of TH gene expression may be one of the mechanisms involved in dopamine transmission control by neurotensin. It has been suggested that the observed changes may likewise participate in adaptation processes at central nervous system where neurotensin is released, such as food intake and stress condition [56].

1 To sum up, the key lines of evidence for the co-ordinate functions of the
2 dopamine and neurotensin systems under stress condition arise from
3 immunocytochemical studies. Within this context, the areas more critically involved are
4 the ventral tegmental area, the central amygdaloid nucleus, the mesotelencephalus and
5 the medial prefrontal cortex.
6
7

8
9 These examples clearly illustrate the close interrelation between the
10 neurotensinergic and the dopaminergic systems and, in turn, both with the HPA axis.
11 Corticosteroids released during stress are able to activate the reward systems inducing
12 an increase of DA release, especially in the nucleus accumbens. The effect of
13 neurotensin on ventral mesencephalic DA, oppose the action of DA, which, via DA
14 autoreceptors, decreases DA neuron activity and reduces DA release in the NAc.
15 Therefore NT is regarded as a modulator of mesotelencephalic DA that might have a
16 crucial role in stress behaviours.

25 **Concluding remarks**

26
27 In the present article available experimental evidence was reviewed, which
28 shows close interaction between dopamine D2 and neurotensin NTS1 receptors,
29 supporting a functional link between these macromolecules under stress condition.
30
31

32
33 There is the notion that stress occurs in response to factors (stressors) being
34 threatening, aversive or excessive to maintain the physiological equilibrium of an
35 organism. It is observed that reiterate exposure to stressors, especially during early life,
36 is often related to later psychiatric disorders. One of the potential candidate mechanisms
37 is the HPA axis, with excessive release of cortisol from adrenal cortex. This process is
38 closely related to several neuroactive substances, including amino acid
39 neurotransmitters, catecholamines, and serotonin as well as neuroactive peptides.
40
41
42
43
44

45
46 Stress conditions are likewise related to neurogenesis and neuroplasticity and
47 generation of free radicals which lead to oxidative stress. It should be taken into
48 consideration the activation of the limbic-HPAaxis and the release of glucocorticoids is
49 fundamental for the adaptive response and immediate survival of an organism in
50 response to acute stimuli. However, high levels of glucocorticoids in brain may lead to
51 neuronal injury and affecting neurotransmitter signaling, neural activity and animal
52 behavior.
53
54
55
56
57

58
59 Evidence indicates that dysregulation of the brain emotional systems that mediate
60 stress and arousal is a key component of the pathophysiology of drug addiction.

Therefore, information provided in the present article may be of interest to unveil molecular mechanisms involved in drug addiction. It would be of interest to investigate whether a correlation exists between drug withdrawal and reward through corticotrophin-releasing factor, dopamine release in nucleus accumbens and neurotensinergic system.

It is desirable that basic research throw light about the molecular mechanisms involved in catecholamine and neurotensin neurotransmission as well as on the cross-talk between dopaminergic D2 receptor and neurotensinergic NTS1 receptor. Another line of research might be focused on signaling resulting of dopamine D2 and NTS1 receptors activation as a cause of stress. These notions will allow introducing specific and selective pharmacological approaches leading to tools which may be preventive or therapeutic for psychiatric illnesses produced by stress conditions (see [57]).

It is expected that the focus in the present review, namely neurotensin and dopamine may allow to draw attention on relevant relations among these neurotransmitters to disclose the mechanisms that control stress behaviour.

8 Schematic representation of the main A) dopaminergic and B) neurotensinergic
9 pathways in the rat brain. It should be noted that both neurotransmitters are localized in
10 areas that are related to the response to stress (such as hypothalamic nucleus), as well as
11 in areas that process emotion (such as amygdala nuclei) and/or cognition (such as
12 hippocampal nuclei and cortical areas). DFC: Dorsal Frontal Cortex. PFC: Prefrontal
13 Cortex. Hip: Hippocampus. Cpu: Caudate Putamen. Nac: Nucleus Accumbens. SN:
14 Sustantia Nigra. VTA: Ventral Tegmental Area. ENT Cx: Entorhinal Cortex. LS:
15 Lateral Septum. PIR: Piriform area. Amy: Amygdala.
