### Abstract

*Senecio* L. s.str. is the largest genus in the tribe Senecioneae (Asteraceae) and it has been commonly characterized by its truncate, penicillate stylar tips, separated stigmatic lines, and stamens usually with ecaudate anther bases and balusterform filament collar. A micromorphological study was carried out to determine if South American species of *Senecio* s.str. present these diagnostic micromorphological characters, as a contribution towards a circumscription of this genus supported by morphology. The study included 72 South American *Senecio* species from eight sections and 16 series, as well as species from six other genera of subtribe Senecioninae (*Delairea*, *Dendrophorbium*, *Dendrosenecio*, *Graphistylis*, *Lomanthus*, *Pentacalia*), three genera of subtribe Tussilaginatae (*Aequatorium*, *Nordenstamia*, *Roldana*), and one of subtribe Brachyglottidinae (*Acrisione*). The studied characters include: style branches (stigmatic surface, and apices), anthers (filament collar, bases, and appendages), as well as pollen features (shape, size, and sculpture). Analyses of these characters suggested that *Senecio* s.str. can be defined only by the presence of balusterform filament collars, which are present in 61 out of the 72 studied *Senecio* s.str. species (vs. cylindrical collar in remaining species). The genera *Graphistylis* and *Delairea* also show this trait, however, *Graphistylis* presents some microcharacters (e.g. “banded” stigmatic surface) that are rather infrequently found in *Senecio* s.str. *Senecio grandis* showed cylindrical collars and sagittate anther bases and should be excluded from the genus. The other microcharacters analyzed appeared to be taxonomically uninformative, since their predominant states were found in *Senecio* s.str. as well as in other genera of Senecioneae.

**Key Words:** *Acrisione*, *Aequatorium*, anthers, *Delairea*, *Dendrophorbium*, *Dendrosenecio*, *Graphistylis*, *Lomanthus*, *Nordenstamia*, *Pentacalia*, pollen, *Roldana*, *Senecio*, stigma, taxonomy

### Introduction

The variable generic and sectional concepts applied by different authors to *Senecio* Linnaeus (Asteraceae, Senecioneae) have long been recognized as a major taxonomic problem in the genus. According to Cabrera (1949, 1957, 1985) and Jeffrey *et al.* (1977), *Senecio* s.l. comprises ca. 3000 species of cosmopolitan distribution, with a high diversity in mountainous areas and deserts of America, Africa, and Asia, being scarcely represented in the wet tropics. On the contrary, several authors have removed numerous species from *Senecio* s.l. and placed them in new genera, or raised to the genus rank previously recognized sections within *Senecio* s.l., e.g. *Aequatorium*, *Aetheolaena*, and *Dendrosenecio* (Robinson & Brettell 1973a, 1973b, 1973c, Robinson 1974, Nordenstam 1978, Cuatrecasas 1981, Jeffrey & Chen 1984, Jeffrey 1986, 1992, Nordenstam *et al.* 2009). Most of the new taxa were established on the basis of micromorphological characters, such as the configuration of the endothelial cells in the filament collar of anthers, the distribution of the stigmatic area on the style branches, the presence of calcium oxalate crystals in the ovary, and the structure of the carpodium cells (Wetter 1983, Vincent 1996). As circumscribed by Nordenstam (2007), the genus *Senecio* s.str. includes at present about 1250 species of cosmopolitan distribution, distinguished by its style branches truncate with short sweeping hairs, separated stigmatic lines, and stamens with ecaudate anther bases and a balusterform filament collar (Nordenstam 2007). On the basis of molecular studies, Pelsner *et al.* (2007) proposed a new delimitation of *Senecio* containing ca. 1000 species distinguished mainly by style tips truncate with short sweeping-hairs, sometimes with a median hair pencil. In this new circumscription, species of six genera i.e. *Aetheolaena* Cassini, *Culcitium*

Humboldt & Bonpland, *Hasteola* Rafinesque, *Iocenes* B. Nordenstam, *Lasiocephalus* Willdenow ex Schlechtendal, and *Robinsonia* Candolle, were transferred to *Senecio*, whereas eight species or species assemblages (four of them from South America, i.e. *Senecio arnaldii* Cabrera, *S. otites* Kunze ex Candolle, *S. ayopayensis* Cuatrecasas-*S. subnemoralis* Dusén group and *S. adamantinus* Bongard-*S. hemmendorffii* Malme-*S. stigophlebius* Baker group) formerly placed in *Senecio* s.l. were removed from this genus.

South America is the most diverse area of *Senecio* with about 500 species, followed by Africa with approximately 350 species (Bremer 1994). South American species have played an important role in the early taxonomic history of *Senecio*, with several relevant taxonomic and floristic contributions made by Cabrera (1949, 1954, 1957, 1985), Cuatrecasas (1950, 1951), Vision & Dillon (1996), Cabrera *et al.* (1999), Beltrán *et al.* (2007), Cabrera & Freire (2009), and Freire *et al.* (2014).

The objective of this study was to determine if *Senecio* s.str. presents micromorphological characters that could be considered diagnostic, as a contribution to define morphologically the circumscription of *Senecio* s.str. suggested by Pelser *et al.* (2007) based upon molecular analyses. To accomplish this, we examined several microcharacters, such as style branches (stigmatic surface, style-branch apices), anthers (filament collar, anther bases, anther appendages), and pollen (shape, size and sculpture) in 72 South American species of *Senecio* (including *S. adamantinus*, *S. hemmendorffii*, *S. otites*), which were chosen because of the high number of species they represent within *Senecio*, and ten genera previously included in *Senecio*.

## Materials & Methods

### *Studied Material*

Microcharacters of styles, anthers, and pollen were analyzed for a total of 72 South American *Senecio* species from eight sections and 16 series, representing seven of 16 of the Andean sections according to Cuatrecasas (1951), 29 of 36 southern South American sections according to Cabrera (1939, 1949, 1957, 1985) and Cabrera *et al.* (1999) (*S. sect. Delairea* as *Delairea*; *S. sect. Dichroa* as *Graphistylis*; *S. sect. Myriocephalus* as *Dendrophorbium*) and 17 of 18 series according to Cabrera (1985) and Cabrera *et al.* (1999) (*S. ser. Myriocephali* as *Dendrophorbium*); 26 of these species were included in molecular studies (Pelser *et al.* 2007). The type species of each infrageneric taxon (except for *S. sect. Cacaliastrum*, *S. sect. Latiflori* and *S. sect. Paranenses*) was included in the study; additional species were analyzed for the most species-rich taxa (i.e. *S. sect. Senecio*). In order to examine the taxonomic value of the characters, ten species, six of them belonging to other genera of subtribe Senecioninae (*Delairea*, *Dendrophorbium*, *Dendrosenecio*, *Graphistylis*, *Lomanthus*, *Pentacalia*), three belonging to genera of subtribe Tussilaginatae (*Aequatorium*, *Nordenstamia*, *Roldana*), and one of subtribe Brachyglottidinae (*Acrisione*), were also sampled. The study was based on herbarium material from CTES, CORD, LP, MO, NY, SI (abbreviations according to Thiers 2016). A list of studied genera, infrageneric taxa, species with their respective authors, and examined specimens is provided in Table 1.

### *Styles & Anthers*

Mature, fully developed disc florets (5–10 florets per specimen) were selected for the analysis. Herbarium samples were rehydrated in warm soapy water and fixed in FAA. Anthers and styles were dissected, clarified with diluted chlorine 5% and stained with Safranin 80%, and samples were mounted in glycerin 60%. Observations were done with LM (Light Microscope) Nikon Microphot-FXA, equipped with a photographic camera, and Gemalux equipped with a photographic camera PAL CCD with Hyper Media Center software.

Scanning Electron Microscopy observations with SEM (scanning electron microscopy) were done on selected styles from the material. For SEM observations, samples were rehydrated with warm soapy water and fixed with FAA. Disc florets were dehydrated in a graded series of ethanol and criticalpoint-dried with Electron Microscopy Sciences-EMS 850. Dried samples were partially dissected, mounted on stubs, sputter-coated with gold/palladium (Mini Sputter SC 7620) and observed with SEM (PHILIPS XL30).

### *Pollen*

Immature disc florets (5–20 florets per specimen) were selected for acetolysis. The acetolysis was performed following the protocol presented by Erdtman (1960) with some modifications. The samples were mounted in semi-permanent medium (distilled water, gelatin, glycerin, and phenol). Observations were done with LM (Light Microscope) Nikon Microphot-FXA, equipped with a photographic camera.

Scanning Electron Microscopy observations with SEM (scanning electron microscopy) were done on selected pollen samples. Acetolyzed samples were treated with Hexamethyldisilazane (HMDS) according to the protocol presented by Brown (1993), and mounted on double-sided tape, sputter-coated with gold/palladium (Mini Sputter SC 7620) and observed with SEM (PHILIPS XL30).

## Results and Discussion

### *Style-Branches of Disc Florets*

In all species examined the style-branches are minutely papillate to papillate in the distal half (Fig. 1A) and apically truncate to subconvex. *Senecio vulgaris*, the type species of *Senecio*, has truncate stylar tips dorsally glabrous (Riva *et al.* 2009).

**FIGURE 1.** Style branches (SEM): **A, B, D.** Cleft stigmatic configuration; **C.** Banded stigmatic configuration. **A.** Style-branch showing subconvex apex surrounded by a crown of short and few hairs; **B–D.** Style-branch apex subconvex surrounded by a crown of many and differently long hairs and with apical tuft with many longer hairs. **A.** *Senecio eightsii*; **B.** *S. acanthifolius*; **C.** *S. imbaburensis*; **D.** *S. superandinus*. Scale bars = 100  $\mu$ m.

*Stigmatic surface of the style branches.* Some authors (e.g. Robinson & Brettell 1973c, Nordenstam 1977, Jeffrey *et al.* 1977) consider the extension of the stigmatic area on the style branch to be a useful diagnostic character, e.g. the bands are fused in “cacalioid” Senecioneae and discrete or separate in non-“cacalioid” Senecioneae. According to Wetter (1983), two configurations were found in the taxa examined in the present study. The first one was referred to as a “cleft” by Wetter (1983). In a ‘cleft’ the stigmatic surface has a narrow, longitudinal, medial cleft along the style branches without any apparent morphological distinction between the cells of the ridges and those in the cleft (Fig. 1A, B, D). The cleft stigmatic surface is present in most of the analyzed species (Table 2). In the second configuration, referred to as “banded” by Wetter (1983), there is a conspicuous morphological distinction between the cells of the groove and the cells of the bands (Fig. 1C). This configuration is present in e.g. *Graphistylis organensis*; *Senecio* sect. *Aetheolaena*: *S. imbaburensis*, *S. lingulatus*; *Senecio* sect. *Reflexi*: *S. superandinus*; *Senecio* sect. *Senecio*: *S. canescens*, *S. comosus*, *S. oreophyton*, *S. pflanzii*, *S. serratifolius*, *S. zosterifolius*. The typical “banded” form of *S. vulgaris* (Wetter 1983) was suggested by Riva *et al.* (2009) as a distinguishing character for the genus. However, the “cleft” configuration was found in most of the species of South American *Senecio* here analyzed.

*Style-Branch Apices.* In nearly all taxa examined in the present study, the style branches are apically papillate, and surrounded by a crown of hairs of different lengths (Fig. 1A; Table 2). However, *Graphistylis organensis*, *Nordenstamia fabrisii*, *Senecio* sect. *Acanthifolii*, *Senecio* sect. *Aetheolaena*, *Senecio* sect. *Reflexi*, *Senecio* sect. *Senecio* (*S. cocuyanus*, *S. santanderensis*), have apically a tuft with scanty or many longer hairs (Figs. 2B–D). The style branches apically truncate and penicillate have often been considered a diagnostic character in the taxonomy of *Senecio*. Consequently, many species with stylar branches convex or conical to truncate, apically with an elongated central tuft, were removed from *Senecio* into e.g. *Pseudogynoxys* (Greenman) Cabrera (Cabrera 1950), *Paragynoxys* (Cuatrecasas) Cuatrecasas (Cuatrecasas 1955), *Aequatorium* (Nordenstam 1978), *Aetheolaena* (Nordenstam 1978), *Iocenes* (Nordenstam 1978), *Graphistylis* (Nordenstam 1978), *Lasiocephalus* (Cuatrecasas 1978). However, the value of this character is controversial since the molecular studies of Pelsner *et al.* (2007, Fig. 1) indicate that *Aetheolaena* (= *Senecio* sect. *Aetheolaena*) and *Iocenes* (= *S. acanthifolius*), both without typical style tips, are sunk in *Senecio*. Our observations support this inclusion since we found transitional states in hairs that conform the tuft, ranging from a few short hairs, poorly differentiated into a crown of hairs, to numerous long hairs (Fig. 1), thus this character does not provide reliable taxonomic information.

### Filament Collar

The filament collars (Koyama 1967, Drury 1973, Nordenstam 1978) or anther collars (Robinson & Brettell 1973d, Jeffrey *et al.* 1977) have been used to separate ‘Cacalioid’ Senecioneae (with ‘cylindrical’ collar) from ‘non Cacalioid’ Senecioneae (with ‘balusterform’ collar). The so called ‘balusterform’ collar by Drury (1973) is an elongated filament collar, strongly or somewhat dilated towards the base, broader than the filament (Fig. 2A, C). In the present study, this type was found in two species included in *Senecio* s.l., i.e. *Delairea odorata* and *Graphistylis organensis*, and in most

of the species of *Senecio* s.str. (Table 2). On the other hand, the ‘cylindrical’ filament collar type is very elongated and uniformly thick or slightly thicker than the filament (Fig. 2B). In the present study, this type was found in 11 species included in *Senecio* s.str. (see Table 2).

**FIGURE 2.** Anther collars and anther bases (LM): **A.** *Senecio brasiliensis*: balusterform collar, auriculate base; **B.** *S. comosus*: cylindrical collar, rounded base; **C.** *S. grandis*: balusterform collar, sagittate base. Scale bars = 100  $\mu$ m.

### **Anther Bases**

Anther bases have been considered important diagnostic features of Senecioneae (Jeffrey 1987). Traditionally, obtuse to slightly acute anther bases were considered as diagnostic for *Senecio* (e.g. Cabrera 1949, 1957). In fact, our analysis revealed that 64 species of *Senecio* s.str. (Table 2) have auriculate anthers, i. e. slightly acute (Fig. 2A). In addition, our study shows that only 2 sections include species with rounded anther base, i. e. obtuse (Fig. 2B): *Senecio* sect. *Adamantini* and *S.* sect. *Senecio* (*S.* ser. *Acanthifolii*; *S.* ser. *Culcitium*; *S.* ser. *Haplostichi*; *S.* ser. *Hualtatini*; *S.* ser. *Senecio*; *S.* ser. *Websteria*). As well as most of the species of *Senecio* s.str., many of the species previously included in *Senecio* s.l., i.e. *Acrisione denticulata*, *Delairea odorata*, *Dendrosenecio johnstonii* subsp. *cottonii*, *Graphistylis organensis*, *Lomanthus bangii*, *Nordenstamia fabrisii*, and *Roldana petasitis*, have auriculate anther bases. Sagittate anthers bases (Fig. 2C) distinguish *Senecio grandis* (*S.* sect. *Cacaliastrum*) from the remaining species of *Senecio* s.str. and are also present in *Aequatorium polygonoides*, *Dendrophorbium catharinense*, and *Pentacalia epiphytica*.

### **Anther Appendages**

Jeffrey (1980) mentioned the taxonomic value of the shape of the apical anther appendages, a character not emphasized by other authors. In almost all studied taxa the apex of anther appendages is acute or obtuse (Fig. 3A, B). However, *Senecio comosus* and *S. pavonii*, *S. otites*, and *S. vulgaris* have rounded anther appendages (Fig. 3C). The anther

appendages about twice as long as broad (Fig. 3A) were found in all species included in *Senecio* s.l. (2:1, Table 2). Anther appendages about as long as broad (Fig. 3B) are present in 20 species of *Senecio* s.str. (1:1, Table 2).

**FIGURE 3.** Anther appendages (LM): **A.** *Senecio brasiliensis*: twice as long as broad, acute; **B.** *S. candidans*: as long as broad, obtuse; **C.** *S. comosus*: rounded. Scale bars = 100  $\mu$ m.

### Pollen

*Apertures.* As generally found within the family Asteraceae (Erdtman 1966, Mesfin 1984), the pollen grains of the species examined in the present study were tricolporate.

*Shape, size, and symmetry.* Pollen grains in all investigated taxa were oblate spheroidal to prolate spheroidal in the equatorial view (Erdtman 1969). The size of the pollen grains ranged from 25–30  $\mu$ m (polar axis with spines included), as in *Acrisione denticulata*, *Delairea odorata*, *Nordenstamia fabrisii*, and *Senecio* sect. *Senecio* (*S. vulgaris*, *S. zosterifolius*), to 54–57  $\mu$ m (polar axis with spines included) in *Senecio* sect. *Crassicephali* (*S. burkartii*). In all studied taxa the pollen grains were radially symmetrical and isopolar.

*Spines.* In all studied taxa, the sculpture of the grains was either echinate (spines 3.5–6  $\mu$ m long) or microechinate (spinules 1–3  $\mu$ m long). Except for *Dendrosenecio johnstonii* subsp. *cottonii* and *Delairea odorata*, the species previously segregated from *Senecio* and here studied have echinate grains. Within *Senecio* s.str., *S.* sect. *Aetheolaena* was the only section in the present study where all the sampled species had microechinate grains (Fig. 4A). In *S.* sect. *Senecio* we found microechinate and echinate grains in same proportion.

The length vs. basal width ratio of the spines ranged from 0.6 in *Senecio neeanus* to 3 in *S. candollei*, with the majority of the species having ratio range between 0.8 and 1.5. In all taxa analyzed the shape of the spines is conical as was previously mentioned by Vincent & Getliffe Norris (1989) for African species of *Senecio*. However, in some taxa we found an interesting variation of this conical shape when length, width, and apex are considered: typically conical (in most of the taxa analyzed), and three additional types here called conical linear, present in *S. eightsii* (Fig. 4B); conical mamelliform, present in *Graphistylis organensis* (Fig. 4C), *Pentacalia ephiphytica* and *Senecio* ser. *Chilenses* (*S. chilensis*, *S. polyphyllus*); this type was also observed in some taxa of tribe Liabeae by Dillon *et al.* (2009); and conical curved, present in *Senecio* sect. *Acanthifolii* (*S. acanthifolius*, Fig. 4D). Under the Light Microscope (LM) we found that the spine bases were perforated, but this character was verified with SEM only for *S. candidans* (Fig. 4E, F), *S. aspericaulis* and *S. niveo-aureus*. Details of pollen morphological features studied in *Senecio* s.str. and the additional genera are showed in Table 3.

**FIGURE 4.** Pollen grains (SEM). **A.** *Senecio involucratus*: microechinate grain; **B.** *S. eightsii*: conical linear spine; **C.** *Graphistylis organensis*: conical mamelliform spine; **D.** *S. acanthifolius*: conical curved spine; **E.** *S. candidans*: echinate grain; **F.** *S. candidans*: conical spine. Scale bars: A, E = 10  $\mu\text{m}$ ; C = 8  $\mu\text{m}$ ; B, D, F = 2  $\mu\text{m}$ .

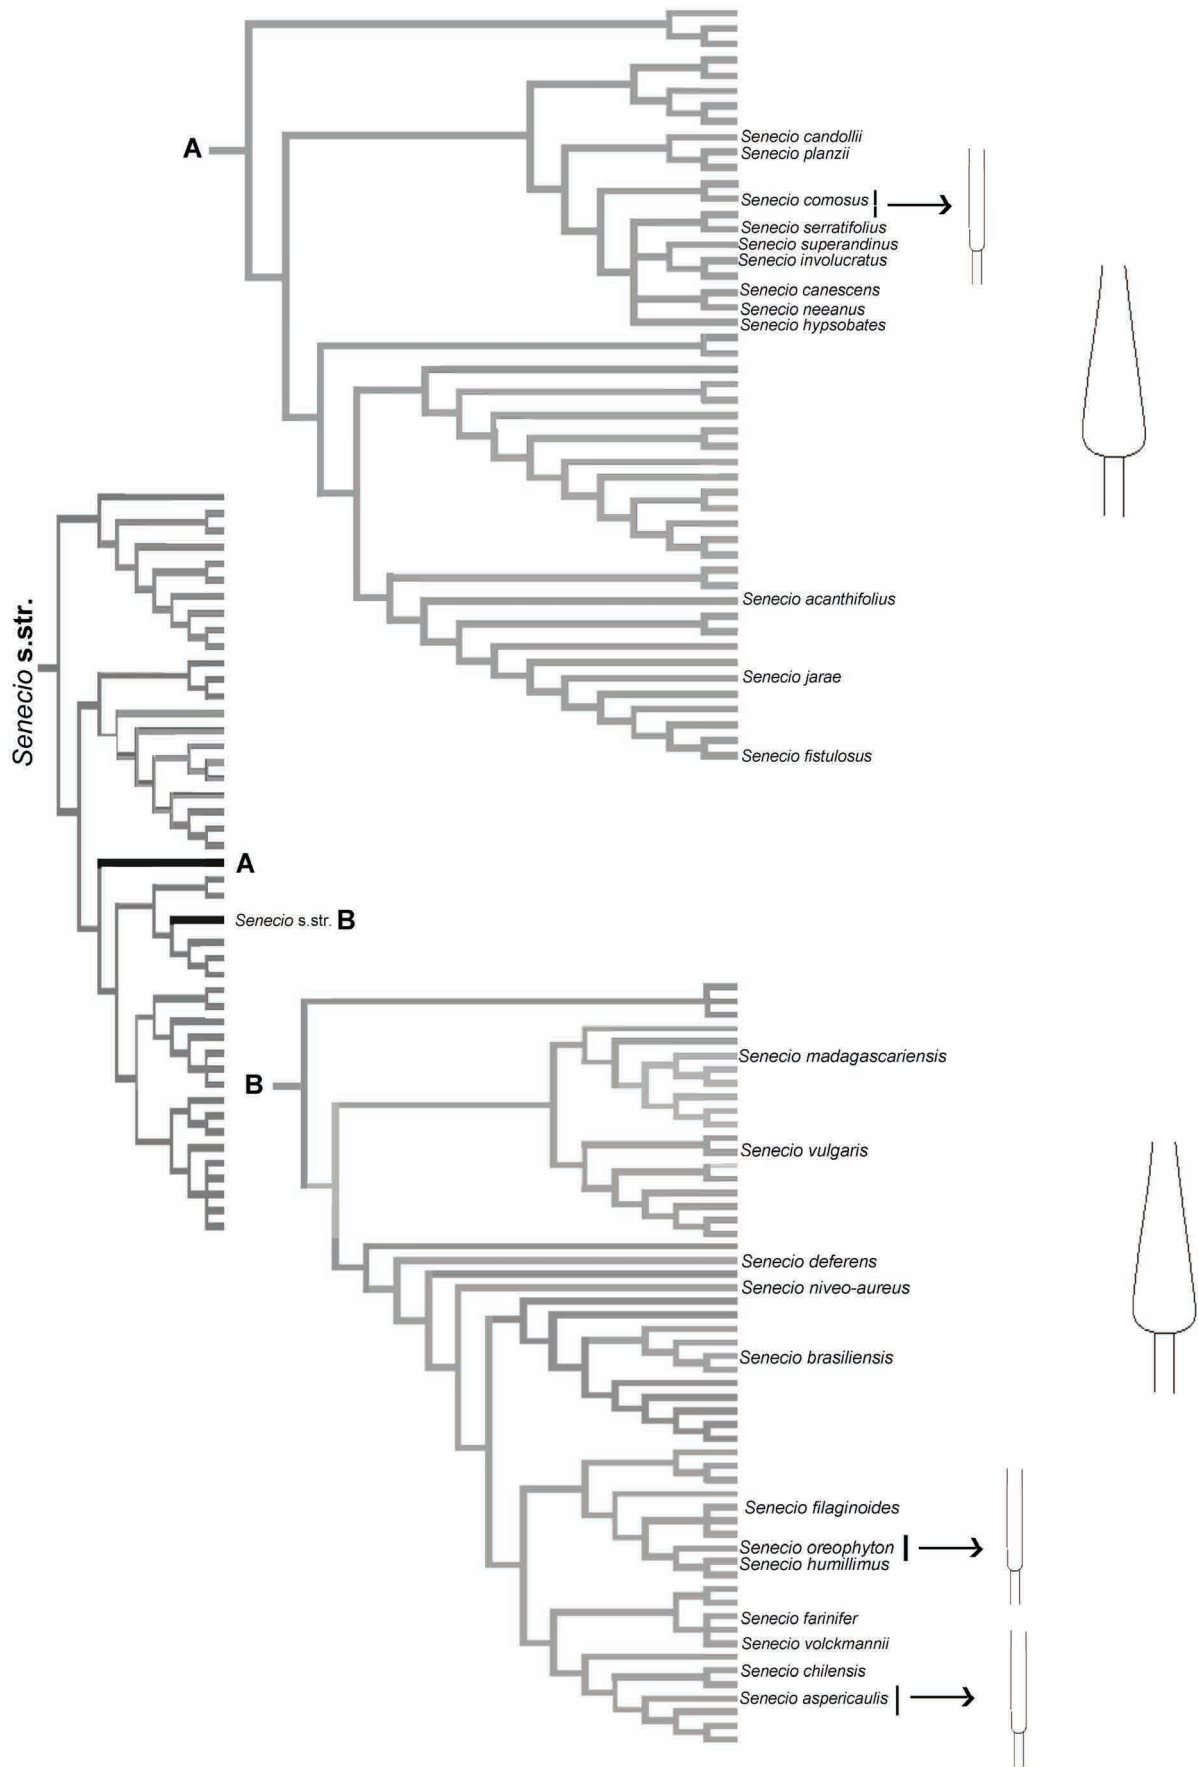

FIGURE 5. Phylogeny of *Senecio s.str.* (modified from Pelser *et al.* 2007) showing configuration of filament collars for 23 of 72 species sampled in the present study.

## Taxonomic Considerations and Conclusions

Considering the micromorphological characters analyzed in our study, only the shape of the anther filament collars showed systematic value. In fact, 61 out of the 72 studied species of *Senecio* s.str. (including *S. vulgaris*, the type species of the genus) present balusterform filament collars; this trait was not found in eight out of the ten analyzed genera of Senecioneae (i.e. *Acrisione*, *Aequatorium*, *Dendrophorbium*, *Dendrosenecio*, *Lomanthus*, *Nordenstamia*, *Pentacalia*, and *Roldana*), so it would allow to circumscribe *Senecio* s.str., at least from the perspective of the South American species sampled; furthermore, balusterform collars are also predominantly found in European, African and Assian species of *Senecio* s.str. (Nordenstam 1978, Pelser *et al.* 2007). Balusterform collars are also present in the genera *Graphistylis* and *Delairea*; however, the former shows features that are rather infrequently found in *Senecio* s.str., e.g. banded stigmatic surfaces, and conical mamelliform pollen spines; furthermore, the segregation of *Graphistylis* from *Senecio* s.str. is also supported by molecular studies (Pelser *et al.* 2007). Even if *Delairea* shares all the studied micromorphological characters with *Senecio* s.str., molecular analyses (Knox & Palmer 1995) showed that this genus is nested in a clade with genera distantly related from *Senecio* s.str., which in some cases present typical anthers of *Senecio* s.str., e.g. *Jacobaea* (incl. *Senecio jacobaea* L. with balusterform collar), and *Gynura* (subcylindric collar present in *G. aurantica* (Blume) DC.). Some of the species of *Senecio* s.str. that have cylindrical filament collars, i.e. *S. aspericaulis*, *S. comosus*, and *S. oreophyton*, lie within the clade of *Senecio* s.str. in previous molecular studies (Pelser *et al.* 2007); this fact could be considered a reversal to the plesiomorphic condition. *Senecio grandis* should be excluded from the genus considering the concurrence of cylindrical collars and sagittate anther bases. However, further phylogenetic analyses are required to confirm the position of *Senecio grandis* as well as the remaining species with cylindrical collars (*S. burkartii*, *S. calocephalus*, *S. hieracium*, *S. pseudaspericaulis*, *S. subdiscoideus*, *S. subpubescens*, and *S. websteri*), which so far have not been included in molecular studies. Other analyzed micromorphological features previously considered valuable in terms of circumscribing *Senecio* s.str. (cfr. Robinson & Brettell 1973c, Nordenstam 1977, Jeffrey *et al.* 1977, Jeffrey 1980, Nordenstam 2007) appeared to be taxonomically uninformative as their predominant states are shared by *Senecio* s.str. and all the other genera studied. In fact, our study shows that the style-branch apices are mainly papillate and surrounded by a crown of hairs of different lengths (the style-branch apices with apical central hair tuft having been found in *Senecio* s.str. as well as in some of the segregated genera), whereas the stigmatic surfaces are mostly cleft; the anther bases are predominantly auriculate, and the anther appendages are mostly twice as long as broad. The pollen characters here examined in search of additional diagnostic traits also did not provide valuable taxonomic information.

Table 4 shows a morphological comparison between *Senecio* s.str. and other genera studied for all analyzed features, and Figure 5 shows the species of *Senecio* s.str. analyzed in the present study that were included in the molecular phylogenetic analysis of Pelser *et al.* (2007).

## Acknowledgments

We give special thanks to Fernando O. Zuloaga and Lone Aagesen for their valuable comments and critical reading of the manuscript. We are very grateful to Celina Fernández from Palynology and Paleobotany Laboratory FCEyN (UBA) for training at acetolysis protocol and useful comments. Special thanks to Gustavo Daujotas from FFyL (UBA) and Raúl Pozner (SI) for their help with the terminology in Latin. Thanks to the curators of CTES, CORD, LP, MO, NY, and SI herbaria for providing the specimens that made this study possible. Support for this work by the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina, is gratefully acknowledged.
