

Asymptotic behavior and zero distribution of polynomials orthogonal with respect to Bessel functions

Alfredo Deaño*, Arno B.J. Kuijlaars†, and Pablo Román‡

May 5, 2018

Abstract

We consider polynomials P_n orthogonal with respect to the weight J_ν on $[0, \infty)$, where J_ν is the Bessel function of order ν . Asheim and Huybrechs considered these polynomials in connection with complex Gaussian quadrature for oscillatory integrals. They observed that the zeros are complex and accumulate as $n \rightarrow \infty$ near the vertical line $\operatorname{Re} z = \frac{\nu\pi}{2}$. We prove this fact for the case $0 \leq \nu \leq 1/2$ from strong asymptotic formulas that we derive for the polynomials P_n in the complex plane. Our main tool is the Riemann-Hilbert problem for orthogonal polynomials, suitably modified to cover the present situation, and the Deift-Zhou steepest descent method. A major part of the work is devoted to the construction of a local parametrix at the origin, for which we give an existence proof that only works for $\nu \leq 1/2$.

1 Introduction

In this paper we are interested in the polynomials P_n that are orthogonal with respect to the weight function J_ν on $[0, \infty)$, where J_ν is the Bessel function of order $\nu \geq 0$. The Bessel function is oscillatory with an amplitude that decays like $\mathcal{O}(x^{-1/2})$ as $x \rightarrow \infty$, and therefore the moments

$$\int_0^\infty x^j J_\nu(x) dx$$

do not exist. It follows that the polynomials P_n can not be defined by the usual orthogonality property

$$\int_0^\infty P_n(x) x^j J_\nu(x) dx = 0, \quad j = 0, 1, \dots, n-1. \quad (1.1)$$

Asheim and Huybrechs [1] introduced the polynomials P_n via a regularization of the weight with an exponential factor. For each $s > 0$, they consider the monic polynomial $P_n(x; s)$ of degree n that is orthogonal with respect to the weight function $J_\nu(x)e^{-sx}$, in the following sense:

$$\int_0^\infty P_n(x; s)x^j J_\nu(x)e^{-sx} dx = 0, \quad j = 0, 1, \dots, n-1, \quad (1.2)$$

and they take the limit

$$P_n(x) = \lim_{s \rightarrow 0^+} P_n(x; s), \quad (1.3)$$

provided that the limit exists. Since the weight function $J_\nu(x)e^{-sx}$ changes sign on the positive real axis, there is actually no guarantee for existence or uniqueness of $P_n(x; s)$. For the limit (1.3) we therefore also have to assume that $P_n(x; s)$ exists and is unique for n large enough.

The polynomials P_n can alternatively be defined by the moments, since the limiting moments for the Bessel function of order $\nu \geq 0$ are known, namely

$$m_j := \lim_{s \rightarrow 0^+} \int_0^\infty x^j J_\nu(x)e^{-sx} dx = 2^j \frac{\Gamma(\frac{1+\nu+j}{2})}{\Gamma(\frac{1+\nu-j}{2})}, \quad (1.4)$$

see [1, section 3.4]. Thus we have the determinantal formula (which is familiar from the general theory of orthogonal polynomials)

$$P_n(x) = \frac{1}{\Delta_n} \begin{vmatrix} m_0 & m_1 & \cdots & m_{n-1} & m_n \\ m_1 & m_2 & \cdots & m_n & m_{n+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ m_{n-1} & m_n & \cdots & m_{2n-2} & m_{2n-1} \\ 1 & x & \cdots & x^{n-1} & x^n \end{vmatrix} \quad (1.5)$$

with a Hankel determinant $\Delta_n = \det [m_{i+j}]_{i,j=0}^{n-1}$. The polynomial P_n thus exists if and only if $\Delta_n \neq 0$.

Asheim and Huybrechs [1] analyze Gaussian quadrature rules with oscillatory weight functions, such as complex exponentials, Airy and Bessel functions. The nodes for the Gaussian quadrature rule are the zeros of the orthogonal polynomials. Since the weight is not real and positive on the interval of orthogonality there is a problem of existence and uniqueness of the orthogonal polynomials. In addition, even when the orthogonal polynomial exists, its zeros may not be real, and they may distribute themselves on some curve or union of curves in the complex plane as the degree tends to infinity. Examples of this kind of behavior are known in the literature, for instance with Laguerre or Jacobi polynomials with non-standard parameters, see [2], [14] and [16], and for complex exponentials [4].

In the present case, with orthogonality defined as (1.2)–(1.3), it was shown in [1, Theorem 3.5] that the zeros of P_n are on the imaginary axis in case $\nu = 0$ and n is even. Namely, if $t_1, \dots, t_{n/2}$ are the zeros of the orthogonal polynomial of degree $n/2$ (where

Figure 1: Plot of the zeros of the polynomials P_n for $n = 200$ and $\nu = 0.25$ (left), $\nu = 0.5$ (right).

n is even) with respect to the positive weight $K_0(\sqrt{t})t^{-1/2}$ on $[0, \infty)$, then the zeros of P_n are $\pm i\sqrt{t_1}, \dots, \pm i\sqrt{t_n/2}$. Here K_0 is the modified Bessel function of the second kind.

For $\nu > 0$ the zeros of P_n are not on the imaginary axis, as is clear from the illustrations given in [1], see also the Figures 1 and 2. The computations have been carried out in MAPLE, using extended precision. From these numerical experiments Asheim and Huybrechs [1] concluded that the zeros seem to cluster along the vertical line $\operatorname{Re} z = \frac{\nu\pi}{2}$. More precisely, for $\nu \leq \frac{1}{2}$, one sees in Figure 1 that the vast majority of zeros are near a vertical line, which is indeed at $\operatorname{Re} z = \frac{\nu\pi}{2}$.

For $\nu > \frac{1}{2}$ one sees in Figure 2 that the zeros with large imaginary part are close to the vertical line $\operatorname{Re} z = \frac{\nu\pi}{2}$, although they are not as close to the vertical line as the zeros in Figure 1.

We were intrigued by these figures and the aim of this paper is to give a partial explanation of the observed behavior of zeros. We are able to analyze the polynomials P_n when $0 \leq \nu \leq \frac{1}{2}$ in the large n limit by means of a Riemann-Hilbert analysis. The result is that we indeed find that the real parts of most of the zeros tend to $\frac{\nu\pi}{2}$ as $n \rightarrow \infty$.

We are not able to handle the case $\nu > \frac{1}{2}$, since in this case our method to construct a local parametrix at the origin fails. This difficulty may very well be related to the different behavior of the zeros in the case $\nu > \frac{1}{2}$. It would be very interesting to analyze this case as well. From the figures it seems that there is a limiting curve for the scaled zeros, if we divide the imaginary parts of the zeros by n and keeping the real parts fixed. This limiting curve is a vertical line segment if $\nu \leq \frac{1}{2}$ (this will follow from our results), but we do not know the nature of this curve if $\nu > \frac{1}{2}$.

Figure 2: Plot of the zeros of the polynomials P_n for $n = 200$ and $\nu = 0.8$ (left), $\nu = 1.3$ (right).

2 Statement of main results

2.1 Convergence of zeros

Our first result is about the weak limit of zeros.

Theorem 2.1. *Let $0 < \nu \leq \frac{1}{2}$. Then the polynomials P_n exist for n large enough. In addition, the zeros of $P_n(in\pi z)$ all tend to the interval $[-1, 1]$ and have the limiting density*

$$\psi(x) = \frac{1}{\pi} \log \frac{1 + \sqrt{1 - x^2}}{|x|}, \quad x \in [-1, 1]. \quad (2.1)$$

The convergence of zeros to the limiting density (2.1) is in the sense of weak convergence of normalized zero counting measures. This means that if $z_{1,n}, \dots, z_{n,n}$ denote the n zeros of P_n , then

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^n \delta_{\frac{z_{j,n}}{i\pi n}} = \psi(x) dx$$

in the sense of weak* convergence of probability measures. Equivalently, we have

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^n f\left(\frac{z_{j,n}}{i\pi n}\right) = \int_{-1}^1 f(x) \psi(x) dx$$

for every function f that is defined and continuous in a neighborhood of $[-1, 1]$ in the complex plane.

The weak limit of zeros, if we rescale them by a factor $i\pi n$, exists and does not depend on the value of ν . Theorem 2.1 is known to hold for $\nu = 0$, and we believe that it also holds true for $\nu > \frac{1}{2}$.

Regarding the real parts of the zeros of P_n as $n \rightarrow \infty$, we have the following result.

Theorem 2.2. *Let $0 < \nu \leq 1/2$, and let $\delta > 0$ be fixed. Then there exist $n_0 \in \mathbb{N}$ and $C > 0$ such that for $n \geq n_0$, every zero $z_{j,n}$ of P_n outside the disks $D(0, n\delta)$ and $D(\pm n\pi i, n\delta)$ satisfies*

$$\left| \operatorname{Re} z_{j,n} - \frac{\nu\pi}{2} \right| \leq C\epsilon_n, \quad (2.2)$$

where

$$\epsilon_n = \frac{n^{\nu-1/2}}{(\log n)^{\nu+1/2}}. \quad (2.3)$$

Remark 2.3. For each fixed $\delta > 0$ there are approximately ϵn zeros of P_n in the disks $D(0, n\delta)$ and $D(\pm n\pi i, n\delta)$ as n is large, where

$$\varepsilon = \int_{-1}^{-1+\delta/\pi} \psi(x) dx + \int_{-\delta/\pi}^{\delta/\pi} \psi(x) dx + \int_{1-\delta/\pi}^1 \psi(x) dx.$$

This is a consequence of the weak convergence of zeros, see Theorem 2.1.

Clearly, $\varepsilon \rightarrow 0$ as $\delta \rightarrow 0$, and so it follows from Theorem 2.2 by taking δ arbitrarily small that for all but $o(n)$ zeros one has that the real part tends to $\frac{\nu\pi}{2}$ as $n \rightarrow \infty$.

Remark 2.4. We do not have information about the zeros in the disk $D(0, n\delta)$. In our Riemann-Hilbert analysis we prove the existence of a local parametrix around the origin, but we do not have an explicit construction with special functions. Therefore we cannot analyze the zeros near the origin.

On the other hand, we do have potential access to the extreme zeros in the disks $D(\pm n\pi i, n\delta)$ since the asymptotics of the polynomials $P_n(in\pi z)$ is given in terms of Airy functions. From the figures it seems that the result (2.2) also holds for the extreme zeros, but we omit this asymptotic result in Theorem 2.6, since it does not follow clearly from the construction of the local parametrices in this case.

2.2 Orthogonality of $P_n(in\pi z)$ and discussion

Theorems 2.1 and 2.2 follow from strong asymptotic formulas for the rescaled polynomials

$$\tilde{P}_n(z) = (in\pi)^{-n} P_n(in\pi z). \quad (2.4)$$

These polynomials are orthogonal polynomials on the real line, but with a complex weight function.

Proposition 2.5. *Let $0 \leq \nu < 1$. Then the polynomial \tilde{P}_n is the monic orthogonal polynomial of degree n for the weight*

$$\begin{cases} e^{\nu\pi i/2} K_\nu(-n\pi x), & \text{for } x < 0, \\ e^{-\nu\pi i/2} K_\nu(n\pi x), & \text{for } x > 0, \end{cases} \quad (2.5)$$

on the real line. That is,

$$\int_{-\infty}^{\infty} \tilde{P}_n(z) x^j e^{-\operatorname{sgn}(x)\nu\pi i/2} K_\nu(n\pi|x|) dx = 0, \quad j = 0, 1, \dots, n-1. \quad (2.6)$$

The function K_ν in (2.5) is the modified Bessel function of second kind of order ν . Proposition 2.5 is proved in Section 3.3.

Since $K_\nu(x) \sim x^{-\nu}$ as $x \rightarrow 0$, see for instance [17, 10.30.2], the condition $\nu < 1$ is necessary for the convergence of the integral (2.6) with $j = 0$. In case $\nu = 0$ then (2.5) is the real and positive weight function $K_0(n\pi|x|)$. Then \tilde{P}_n has all its zeros on the real line, and consequently the zeros of P_n are on the imaginary axis. This way we recover the result of [1].

For $\nu = 1/2$, the modified Bessel function reduces to an elementary function and the weight function (2.5) is

$$\begin{cases} e^{\pi i/4}(2n|x|)^{-1/2}e^{-n\pi|x|}, & x < 0, \\ e^{-\pi i/4}(2n|x|)^{-1/2}e^{-n\pi|x|}, & x > 0. \end{cases} \quad (2.7)$$

The weight (2.7) has three components:

- An exponential varying weight $e^{-n\pi|x|}$ with a potential function $V(x) = \pi|x|$ that is convex but non-smooth at the origin.
- A square root singularity at the origin $|x|^{-1/2}$.
- A complex phase factor $e^{\pm\pi i/4}$ with a jump discontinuity at the origin.

The exponential varying weight determines the limiting density (2.1). Indeed we have that $\psi(x)dx$ is the minimizer of the logarithmic energy in external field $\pi|x|$ among probability measures on the real line, see [19], and as is well-known, the zeros of the orthogonal polynomials with varying weight function $e^{-n\pi|x|}$ have ψ as limiting density. This continues to be the case for the weights (2.5) as is claimed by Theorem 2.1. A Riemann-Hilbert analysis for the weight $e^{-n\pi|x|}$, and other Freud weights, is in [13].

The square root singularity and the jump discontinuity are known as Fisher-Hartwig singularities in the theory of Toeplitz determinants. There is much recent progress in the understanding of Toeplitz and Hankel determinants with such singularities [7]. This is also related to the asymptotics of the corresponding orthogonal polynomials, whose local behavior near a Fisher-Hartwig singularity is described with the aid of confluent hypergeometric functions, see the works of Deift, Its and Krasovsky [6, 12] and also [10, 11].

We are facing the complication that the Fisher-Hartwig singularity is combined with a logarithmic divergence of the density ψ at the origin, see (2.1). In our Riemann-Hilbert analysis we were not able to construct a local parametrix with special functions, and we had to resort to an existence proof, where we used ideas from [13] and [3], although our proof is at the technical level different from either of these papers.

2.3 Asymptotic behavior

Away from the region where the zeros of $P_n(z)$ lie, the asymptotic behavior is governed by the g function associated with the limiting density ψ , that is,

$$g(z) = \int_{-1}^1 \log(z-x)\psi(x)dx, \quad (2.8)$$

where the density ψ is given by (2.1). Then g is defined and analytic for $z \in \mathbb{C} \setminus (-\infty, 1]$.

We prove the following asymptotic behavior of P_n in the region away from the zeros. We continue to use ϵ_n as defined in (2.3).

Theorem 2.6. *Let $0 < \nu \leq 1/2$. Then the polynomial P_n exists and is unique for sufficiently large n . Moreover, the polynomial \tilde{P}_n given by (2.4) has the following behavior as $n \rightarrow \infty$:*

$$\tilde{P}_n(z) = e^{ng(z)} \left(\frac{z(z + (z^2 - 1)^{1/2})}{2(z^2 - 1)} \right)^{1/4} \left(\frac{(z^2 - 1)^{1/2} - i}{(z^2 - 1)^{1/2} + i} \right)^{-\nu/4} (1 + \mathcal{O}(\epsilon_n)), \quad (2.9)$$

uniformly for z in compact subsets of $\mathbb{C} \setminus [-1, 1]$. Here the branch of the function $(z^2 - 1)^{1/2}$ is taken which is analytic in $\mathbb{C} \setminus [-1, 1]$ and positive for real $z > 1$.

In a neighborhood of $(-1, 1)$ we find oscillatory behavior of the polynomials \tilde{P}_n as $n \rightarrow \infty$. We state the asymptotic formula (2.12) for $\operatorname{Re} z \geq 0$ only. There is an analogous formula for $\operatorname{Re} z < 0$. This follows from the fact that the polynomial P_n has real coefficients, as all the moments in the determinantal formula (1.5) are real. Thus $P_n(\bar{z}) = \overline{P_n(z)}$, and so

$$\tilde{P}_n(-\bar{z}) = \overline{\tilde{P}_n(z)}, \quad z \in \mathbb{C}.$$

To describe the behavior near the interval, we need the analytic continuation of the density (2.1), which we also denote by ψ ,

$$\psi(z) = \frac{1}{\pi} \log \frac{1 + (1 - z^2)^{1/2}}{z}, \quad \operatorname{Re} z > 0, \quad (2.10)$$

which is defined and analytic in $\{z \mid \operatorname{Re} z > 0\} \setminus [1, \infty)$. For $\operatorname{Re} z > 0$ with $z \notin [1, \infty)$ we also define

$$\theta_n(z) = n\pi \int_z^1 \psi(s) ds + \frac{1}{4} \arccos z - \frac{\pi}{4}. \quad (2.11)$$

Theorem 2.7. *Let $0 < \nu \leq 1/2$. There is an open neighborhood E of $(-1, 1)$ such that for $z \in E \setminus \{0\}$ with $\operatorname{Re} z \geq 0$ we have*

$$\begin{aligned} \tilde{P}_n(z) = \frac{z^{1/4} e^{\frac{\nu\pi i}{4}} e^{n\pi z/2}}{2^{1/4} (2e)^n (1 - z^2)^{1/4}} \left[\exp\left(\frac{\nu\pi}{2} \psi(z) + i\theta_n(z)\right) \left(1 + \mathcal{O}\left(\frac{\log n}{n}\right)\right) \right. \\ \left. + \exp\left(-\frac{\nu\pi}{2} \psi(z) - i\theta_n(z)\right) \left(1 + \mathcal{O}\left(\frac{\log n}{n}\right)\right) + \mathcal{O}(\epsilon_n) \right] \end{aligned} \quad (2.12)$$

as $n \rightarrow \infty$, with ψ and θ_n given by (2.10) and (2.11). The asymptotic expansion (2.12) is uniform for $z \in E$ with $\operatorname{Re} z \geq 0$ and $|z - 1| > \delta$, $|z| > \delta$, for every $\delta > 0$.

The two terms $\exp\left(\frac{\nu\pi}{2} \psi(z) + i\theta_n(z)\right)$ and $\exp\left(-\frac{\nu\pi}{2} \psi(z) - i\theta_n(z)\right)$ in (2.12) describe the oscillatory behavior near the interval as well as the leading order behavior of the zeros. Zeros can only happen when these two terms are of comparable absolute value so that cancellations can take place. When $\nu = 0$ this happens for real $z \in E$. However, for $\nu > 0$ this does not happen for real z , but near the line $\operatorname{Im} z = -\frac{\nu}{2n}$, as we will show in Section 4.4. This leads to Theorem 2.2.

2.4 Outline of the paper

The structure of the rest of the paper is as follows. In Section 3 we state the Riemann–Hilbert problem $Y^{(s)}$ for $P_n(x; s)$ with $s > 0$, and we make an initial transformation

$$Y^{(s)} \mapsto X^{(s)}.$$

In the RH problem for $X^{(s)}$ we can take the limit $s \rightarrow 0+$ which leads to a RH problem for X , that characterizes the polynomial $P_n(x)$. Then we carry out the further transformations

$$X \mapsto U \mapsto T \mapsto S \mapsto Q \mapsto R$$

of the Deift–Zhou nonlinear steepest descent method [5, 8]. The step $X \mapsto U$ is rotation and scaling, to translate the problem to the interval $[-1, 1]$. This leads to the polynomials \tilde{P}_n and the proof of Proposition 2.5. The normalization at ∞ in the $U \mapsto T$ step is carried out using an equilibrium problem with a Freud weight $w(x) = e^{-nV(x)}$, where $V(x) = \pi|x|$ is the pointwise limit as $n \rightarrow \infty$ of the varying weight

$$V_n(x) = -\frac{1}{n} \log K_\nu(n\pi|x|).$$

The construction of the global parametrix N on the interval $[-1, 1]$ involves two Szegő functions $D_1(z)$ and $D_2(z)$, that correspond respectively to an algebraic singularity of the weight function at the origin and to a complex phase factor. The local parametrices near the endpoints ± 1 involve Airy functions, since the density $\psi(x)$ in (2.1) behaves like a square root in a neighborhood of these endpoints. The main difficulty of the analysis is the construction of a local parametrix in a neighborhood of the origin, and the reason is the lack of analyticity of the weight function $V_n(x)$ in that neighborhood. In this paper, we reduce the jump matrices in that local analysis to almost constant in a disk around 0 and then use a small norm argument in $L^2 \cap L^\infty$ to prove existence of a solution to this local RH problem. In this respect, the analysis is similar to the one presented by Kriecherbauer and McLaughlin in [13]. Also, the same limiting potential $V(x)$ appears in the work of Bleher and Bothner in [3]. Another example of non-analytic weight function was considered in the work of Foulquié, Martínez–Finkelshtein and Sousa, see [10] and [11], although in this case the local parametrix at the origin is explicitly given in terms of confluent hypergeometric functions.

Finally, in Section 4 we follow the transformations both outside and inside the lens, but away from the origin, to get the asymptotic information about $P_n(z)$ and its zeros. This proves Theorem 2.6 and 2.7. Theorem 2.1 follows from Theorem 2.6 and Theorem 2.7 is a consequence of 2.2.

3 Riemann–Hilbert problem

3.1 RH problem for polynomials $P_n(x; s)$

We let $\nu > 0$ and $s > 0$. Orthogonal polynomials are characterized by a matrix valued Riemann–Hilbert problem as was first shown by Fokas, Its, and Kitaev [9], see also [5].

This characterization does not use the fact that the orthogonality weight is non-negative, and it therefore also applies to oscillatory weights. Thus the polynomial $P_n(x; s)$ satisfying (1.2) is characterized by the following Riemann-Hilbert problem:

RH problem 3.1. $Y^{(s)} : \mathbb{C} \setminus [0, \infty) \rightarrow \mathbb{C}^{2 \times 2}$ is a 2×2 matrix valued function that satisfies:

- 1) $Y^{(s)}$ is analytic in $\mathbb{C} \setminus [0, \infty)$.
- 2) $Y^{(s)}$ satisfies the jump condition

$$Y_+^{(s)}(x) = Y_-^{(s)}(x) \begin{pmatrix} 1 & J_\nu(x)e^{-sx} \\ 0 & 1 \end{pmatrix} \quad \text{on } (0, \infty).$$

- 3) As $z \rightarrow \infty$,

$$Y^{(s)}(z) = (I + \mathcal{O}(1/z)) \begin{pmatrix} z^n & 0 \\ 0 & z^{-n} \end{pmatrix}, \quad (3.1)$$

where I denotes the 2×2 identity matrix.

- 4) $Y^{(s)}(z)$ remains bounded as $z \rightarrow 0$.

The polynomial $P_n(x; s)$ exists and is unique if and only if the RH problem has a unique solution. In that case we have

$$P_n(x; s) = Y_{11}^{(s)}(x). \quad (3.2)$$

3.2 First transformation

In the first transformation we use the following connection formula between J_ν and the modified Bessel function K_ν of the second kind:

$$J_\nu(z) = \frac{1}{\pi i} \left(e^{-\frac{\nu\pi i}{2}} K_\nu(-iz) - e^{\frac{\nu\pi i}{2}} K_\nu(iz) \right), \quad |\arg z| \leq \frac{\pi}{2}, \quad (3.3)$$

see for instance [17, formula 10.27.9]. Alternatively, the Bessel function can be written in terms of Hankel functions as in [17, formula 10.4.4].

The formula (3.3) leads to the following factorization of the jump matrix:

$$\begin{pmatrix} 1 & J_\nu(x)e^{-sx} \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & -\frac{e^{-\frac{\nu\pi i}{2}}}{\pi i} K_\nu(ix)e^{-sx} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{e^{-\frac{\nu\pi i}{2}}}{\pi i} K_\nu(-ix)e^{-sx} \\ 0 & 1 \end{pmatrix}. \quad (3.4)$$

We define the new matrix valued function $X^{(s)}$ by

$$X^{(s)}(z) = \begin{cases} \begin{pmatrix} 1 & 0 \\ 0 & (\pi i)^{-1} \end{pmatrix} Y^{(s)}(z) \begin{pmatrix} 1 & -e^{-\frac{\nu\pi i}{2}} K_\nu(-iz)e^{-sz} \\ 0 & \pi i \end{pmatrix}, & \text{if } 0 < \arg z < \frac{\pi}{2}, \\ \begin{pmatrix} 1 & 0 \\ 0 & (\pi i)^{-1} \end{pmatrix} Y^{(s)}(z) \begin{pmatrix} 1 & -e^{\frac{\nu\pi i}{2}} K_\nu(iz)e^{-sz} \\ 0 & \pi i \end{pmatrix}, & \text{if } -\frac{\pi}{2} < \arg z < 0, \\ \begin{pmatrix} 1 & 0 \\ 0 & (\pi i)^{-1} \end{pmatrix} Y^{(s)}(z) \begin{pmatrix} 1 & 0 \\ 0 & \pi i \end{pmatrix}, & \text{elsewhere.} \end{cases} \quad (3.5)$$

Then $X^{(s)}$ has an analytic continuation across the positive real axis, due to the factorization (3.4). Thus $X^{(s)}$ is defined and analytic in the complex plane except for the imaginary axis, and it satisfies the following RH problem:

RH problem 3.2. 1) $X^{(s)}$ is analytic in $\mathbb{C} \setminus i\mathbb{R}$.

2) $X^{(s)}$ satisfies the jump condition (the imaginary axis is oriented from bottom to top)

$$X_+^{(s)}(x) = X_-^{(s)}(x) \begin{cases} \begin{pmatrix} 1 & e^{-\frac{\nu\pi i}{2}} K_\nu(-ix)e^{-sx} \\ 0 & 1 \end{pmatrix}, & \text{for } x \in (0, +i\infty), \\ \begin{pmatrix} 1 & e^{\frac{\nu\pi i}{2}} K_\nu(ix)e^{-sx} \\ 0 & 1 \end{pmatrix}, & \text{for } x \in (-i\infty, 0). \end{cases} \quad (3.6)$$

3) As $z \rightarrow \infty$,

$$X^{(s)}(z) = (I + \mathcal{O}(1/z)) \begin{pmatrix} z^n & 0 \\ 0 & z^{-n} \end{pmatrix}. \quad (3.7)$$

4) $X^{(s)}(z)$ remains bounded as $z \rightarrow 0$ with $\operatorname{Re} z < 0$, and

$$X^{(s)}(z) = \begin{pmatrix} \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \end{pmatrix}, \quad \text{as } z \rightarrow 0 \text{ with } \operatorname{Re} z > 0. \quad (3.8)$$

The asymptotic condition (3.7) follows from (3.1), the definition (3.5) and the fact that

$$K_\nu(z) = \left(\frac{\pi}{2z}\right)^{1/2} e^{-z} (1 + \mathcal{O}(1/z)), \quad \text{as } z \rightarrow \infty, \quad |\arg z| < \frac{3\pi}{2}, \quad (3.9)$$

see [17, formula 10.40.2]. The $\mathcal{O}(z^{-\nu})$ terms in (3.8) appear because of the behavior

$$K_\nu(z) \sim \frac{\Gamma(\nu)}{2^{1-\nu}} z^{-\nu} \quad (3.10)$$

as $z \rightarrow 0$ for $\nu > 0$, see for instance [17, formula 10.30.2]. Note that by (3.2) and (3.5)

$$P_n(x; s) = X_{11}^{(s)}(x). \quad (3.11)$$

In the RH problem for $X^{(s)}$ we can take $s \rightarrow 0+$. Indeed, after setting $s = 0$ in (3.6), the off-diagonal entries in the jump matrices still tend to 0 as $|x| \rightarrow \infty$ because of (3.9). We put $s = 0$ and we consider the following RH problem.

RH problem 3.3. We seek a function $X : \mathbb{C} \setminus i\mathbb{R} \rightarrow \mathbb{C}^{2 \times 2}$ satisfying:

1) X is analytic in $\mathbb{C} \setminus i\mathbb{R}$.

2) X satisfies the jump condition (the imaginary axis is oriented from bottom to top)

$$X_+(x) = X_-(x) \begin{cases} \begin{pmatrix} 1 & e^{-\frac{\nu\pi i}{2}} K_\nu(-ix) \\ 0 & 1 \end{pmatrix}, & \text{for } x \in (0, +i\infty), \\ \begin{pmatrix} 1 & e^{\frac{\nu\pi i}{2}} K_\nu(ix) \\ 0 & 1 \end{pmatrix}, & \text{for } x \in (-i\infty, 0). \end{cases}$$

3) As $z \rightarrow \infty$,

$$X(z) = (I + \mathcal{O}(1/z)) \begin{pmatrix} z^n & 0 \\ 0 & z^{-n} \end{pmatrix}.$$

4) $X(z)$ remains bounded as $z \rightarrow 0$ with $\operatorname{Re} z < 0$, and

$$X(z) = \begin{pmatrix} \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \end{pmatrix}, \quad \text{as } z \rightarrow 0 \text{ with } \operatorname{Re} z > 0.$$

If there is a unique solution then the 11-entry is a monic polynomial of degree n , say P_n , and

$$P_n(x) = X_{11}(z) = \lim_{s \rightarrow 0^+} X_{11}^{(s)}(z) = \lim_{s \rightarrow 0^+} P_n(x; s) \quad (3.12)$$

see (3.11). Thus P_n is the polynomial that we are interested in.

3.3 Second transformation

We introduce a scaling and rotation $z \mapsto i\pi n z$ and our main interest is in the rescaled polynomials $P_n(i\pi n z)$ whose zeros will accumulate on the interval $[-1, 1]$ as $n \rightarrow \infty$. More precisely, we define U as

$$U(z) = \begin{pmatrix} (i\pi n)^{-n} & 0 \\ 0 & (i\pi n)^n \end{pmatrix} X(i\pi n z). \quad (3.13)$$

From (3.13) and the RH problem 3.3, we immediately obtain the following RH problem for $U(z)$:

RH problem 3.4. 1) U is analytic in $\mathbb{C} \setminus \mathbb{R}$.

2) U satisfies the jump condition

$$U_+(x) = U_-(x) \begin{cases} \begin{pmatrix} 1 & e^{\nu\pi i/2} K_\nu(n\pi|x|) \\ 0 & 1 \end{pmatrix}, & x \in (-\infty, 0), \\ \begin{pmatrix} 1 & e^{-\nu\pi i/2} K_\nu(n\pi|x|) \\ 0 & 1 \end{pmatrix}, & x \in (0, \infty). \end{cases}$$

3) As $z \rightarrow \infty$,

$$U(z) = (I + \mathcal{O}(1/z)) \begin{pmatrix} z^n & 0 \\ 0 & z^{-n} \end{pmatrix}.$$

4) $U(z)$ remains bounded as $z \rightarrow 0$ with $\text{Im } z > 0$, and

$$U(z) = \begin{pmatrix} \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \end{pmatrix} \quad \text{as } z \rightarrow 0 \text{ with } \text{Im } z < 0.$$

Note that by (3.12), (3.13), and (2.4)

$$U_{11}(z) = (in\pi)^{-n} X_{11}(in\pi z) = (in\pi)^{-n} P_n(in\pi z) = \tilde{P}_n(z) \quad (3.14)$$

which is a monic polynomial of degree n . The zeros of $U_{11}(z)$ are obtained from the zeros of P_n by rotation over 90 degrees in the clockwise direction and by dividing by a factor πn .

We can now prove Proposition 2.5.

Proof of Proposition 2.5. The RH problem for U is the RH problem for orthogonal polynomials on the real line for the varying weight function $e^{\mp\nu\pi i/2} K_\nu(n\pi|x|)$ for $x \in \mathbb{R}^\pm$, see [5, 8, 9]. Because of the $e^{\mp\nu\pi i/2}$ factor, the weight function is not real on the real line, and it has a singularity at the origin because of the behavior (3.10) of the K_ν function near 0. The singularity is integrable since $\nu < 1$, and so $U_{11} = \tilde{P}_n$ is the monic polynomial of degree n satisfying (2.6). \square

3.4 Equilibrium problem and third transformation

In order to normalize the RH problem at infinity we make use of an equilibrium problem with external field $V(x) = \pi|x|$. The equilibrium measure μ minimizes the energy functional

$$I(\mu) = \iint \log \frac{1}{|x-y|} d\mu(x) d\mu(y) + \int \pi|x| d\mu(x)$$

among all probability measures on \mathbb{R} . The minimizer is supported on $[-1, 1]$. It is absolutely continuous with respect to the Lebesgue measure, $d\mu(x) = \psi(x)dx$, and has density

$$\psi(x) = \frac{1}{\pi} \int_{|x|}^1 \frac{1}{\sqrt{s^2 - x^2}} ds,$$

which corresponds to the case $\beta = 1$ in [13]. The integral can be evaluated explicitly and it gives the formula (2.1). Note that $\psi(x)$ grows like a logarithm at $x = 0$.

The g function is defined in (2.8). The boundary values $g_+(x)$ and $g_-(x)$ on the real axis satisfy

$$g_+(x) - g_-(x) = \begin{cases} 2\pi i, & x \leq -1, \\ 2\pi i \int_x^1 \psi(s) ds, & -1 < x < 1, \\ 0, & x \geq 1. \end{cases} \quad (3.15)$$

The Euler-Lagrange equations for the equilibrium problem imply that we have (see e.g. [5] or [19])

$$g_+(x) + g_-(x) - \pi|x| \begin{cases} = \ell, & x \in [-1, 1], \\ < \ell, & x \in (-\infty, -1) \cup (1, \infty). \end{cases} \quad (3.16)$$

with the constant ℓ (see Theorem IV.5.1 in [19] or formula (3.5) in [13])

$$\ell = -2 - 2 \log 2. \quad (3.17)$$

A related function is

$$\varphi(z) = g(z) - \frac{V(z)}{2} - \frac{\ell}{2} \quad (3.18)$$

where

$$V(z) = \begin{cases} \pi z, & \operatorname{Re} z > 0, \\ -\pi z, & \operatorname{Re} z < 0. \end{cases} \quad (3.19)$$

The φ -function is analytic in $\mathbb{C} \setminus ((-\infty, 1] \cup i\mathbb{R})$. For $x \in [-1, 1]$ we have from the variational equation (3.16)

$$\begin{aligned} \varphi_+(x) &= g_+(x) - \frac{V(x)}{2} - \frac{\ell}{2} = \frac{1}{2}(g_+(x) - g_-(x)), \\ \varphi_-(x) &= -\varphi_+(x). \end{aligned} \quad (3.20)$$

Thus 2φ gives an analytic extension of $g_+(x) - g_-(x)$ from $[-1, 1]$ into the upper half plane minus the imaginary axis, and of $g_-(x) - g_+(x)$ into the lower half plane minus the imaginary axis. Note that $\varphi_{\pm}(x)$ is purely imaginary on $[-1, 1]$, because of (3.15).

On the imaginary axis, the function $\varphi(z)$ is not analytic because of the discontinuity in $V(z)$. The boundary values of this weight function satisfy

$$V_-(z) = V_+(z) + 2\pi z,$$

and as a consequence,

$$\varphi_-(z) = \varphi_+(z) - \pi z, \quad z \in i\mathbb{R}.$$

Here we take the orientation of the imaginary axis from bottom to top.

Now we are ready for the third transformation of the RH problem and we define the matrix valued function

$$T(z) = e^{-n\ell\sigma_3/2} (2n)^{\sigma_3/4} U(z) e^{-n(g(z) - \ell/2)\sigma_3} (2n)^{-\sigma_3/4}, \quad (3.21)$$

where $\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ is the third Pauli matrix. We also write

$$W_n(x) = \sqrt{2n} K_\nu(n\pi|x|) e^{n\pi|x|}, \quad x \in \mathbb{R}. \quad (3.22)$$

Then from the above definitions and properties and from the RH problem 3.4 for U we find that T satisfies the following Riemann–Hilbert problem.

RH problem 3.5. 1) T is analytic in $\mathbb{C} \setminus \mathbb{R}$.

2) T satisfies the jump conditions

$$T_+(x) = T_-(x) \begin{cases} \begin{pmatrix} 1 & e^{\nu\pi i/2} W_n(x) e^{2n\varphi_+(x)} \\ 0 & 1 \end{pmatrix}, & x \in (-\infty, -1), \\ \begin{pmatrix} e^{-2n\varphi_+(x)} & e^{\nu\pi i/2} W_n(x) \\ 0 & e^{-2n\varphi_-(x)} \end{pmatrix}, & x \in (-1, 0), \\ \begin{pmatrix} e^{-2n\varphi_+(x)} & e^{-\nu\pi i/2} W_n(x) \\ 0 & e^{-2n\varphi_-(x)} \end{pmatrix}, & x \in (0, 1), \\ \begin{pmatrix} 1 & e^{-\nu\pi i/2} W_n(x) e^{2n\varphi_+(x)} \\ 0 & 1 \end{pmatrix}, & x \in (1, \infty), \end{cases}$$

where W_n is given in (3.22).

3) As $z \rightarrow \infty$,

$$T(z) = I + \mathcal{O}(1/z).$$

4) $T(z)$ remains bounded as $z \rightarrow 0$ with $\text{Im } z > 0$, and

$$T(z) = \begin{pmatrix} \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \end{pmatrix}, \quad \text{as } z \rightarrow 0 \text{ with } \text{Im } z < 0. \quad (3.23)$$

The off-diagonal elements in the jump matrices on $(-\infty, -1)$ and $(1, \infty)$ tend to 0 at an exponential rate, because of the Euler–Lagrange condition (3.16).

3.5 Fourth transformation

The jump matrix on the interval $(-1, 0)$ has a factorization

$$\begin{pmatrix} e^{-2n\varphi_+(x)} & e^{\nu\pi i/2} W_n(x) \\ 0 & e^{-2n\varphi_-(x)} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \frac{e^{-\nu\pi i/2}}{W_n(x)} e^{-2n\varphi_-(x)} & 1 \end{pmatrix} \begin{pmatrix} 0 & e^{\nu\pi i/2} W_n(x) \\ -\frac{e^{-\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \frac{e^{-\nu\pi i/2}}{W_n(x)} e^{-2n\varphi_+(x)} & 1 \end{pmatrix},$$

while the jump matrix on $(0, 1)$ factorizes as

$$\begin{pmatrix} e^{-2n\varphi_+(x)} & e^{-\nu\pi i/2} W_n(x) \\ 0 & e^{-2n\varphi_-(x)} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \frac{e^{\nu\pi i/2}}{W_n(x)} e^{-2n\varphi_-(x)} & 1 \end{pmatrix} \begin{pmatrix} 0 & e^{-\nu\pi i/2} W_n(x) \\ -\frac{e^{\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \frac{e^{\nu\pi i/2}}{W_n(x)} e^{-2n\varphi_+(x)} & 1 \end{pmatrix}.$$

In order to open the lens around $(-1, 1)$, we need the analytic extension of the function W_n from (3.22) to $\mathbb{C} \setminus i\mathbb{R}$, which we also denote by W_n ,

$$W_n(z) = \begin{cases} \sqrt{2n} K_\nu(n\pi z) e^{n\pi z}, & \text{Re } z > 0, \\ \sqrt{2n} K_\nu(-n\pi z) e^{-n\pi z}, & \text{Re } z < 0. \end{cases} \quad (3.24)$$

Figure 3: Opening of a lens around $[-1, 1]$, and contour Σ_S consisting of $\Sigma_1, \dots, \Sigma_4$, the segment $(-i\rho, i\rho)$ and the real line.

Note that as $n \rightarrow \infty$, see (3.9) and (3.24),

$$W_n(z) = \begin{cases} z^{-1/2}(1 + \mathcal{O}(1/(nz))), & \operatorname{Re} z > 0, \\ (-z)^{-1/2}(1 + \mathcal{O}(1/(nz))), & \operatorname{Re} z < 0, \end{cases} \quad (3.25)$$

which explains the factor $\sqrt{2n}$ that we introduced in (3.22) and (3.24).

Next, we fix a number $\rho > 0$ and we open a lens around $[-1, 1]$, which defines contours Σ_j , $j = 1, \dots, 4$ and domains Ω_j , $j = 1, \dots, 4$ as indicated in Figure 3.

In the fourth transformation we define the matrix valued function $S(z)$:

$$S(z) = \begin{cases} T(z) \begin{pmatrix} 1 & 0 \\ -\frac{e^{\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & \text{for } z \in \Omega_1, \\ T(z) \begin{pmatrix} 1 & 0 \\ -\frac{e^{-\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & \text{for } z \in \Omega_2, \\ T(z) \begin{pmatrix} 1 & 0 \\ \frac{e^{-\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & \text{for } z \in \Omega_3, \\ T(z) \begin{pmatrix} 1 & 0 \\ \frac{e^{\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & \text{for } z \in \Omega_4, \\ T(z), & \text{elsewhere,} \end{cases} \quad (3.26)$$

using the analytic extension (3.24) for the function $W_n(z)$ in each region, and $\varphi(z)$ defined in (3.18).

Remark 3.6. In order to divide by $W_n(z)$ we need to be careful with possible zeros of this function in the complex plane. Following the general theory in [21, §15.7], the Bessel function $K_\nu(n\pi z)$ is free from zeros in the half-plane $|\arg z| \leq \frac{\pi}{2}$. Using (3.24), we can conclude that $W_n(z) \neq 0$.

From the RH problem 3.5 and (3.26) we find that that $S(z)$ is the solution of the following RH problem:

RH problem 3.7. 1) S is analytic in $\mathbb{C} \setminus \Sigma_S$, where Σ_S is depicted in Figure 3.

2) S satisfies the jump conditions $S_+ = S_- J_S$ where

$$J_S(z) = \begin{cases} \begin{pmatrix} 1 & 0 \\ \frac{e^{\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & z \in \Sigma_1 \cup \Sigma_4, \\ \begin{pmatrix} 1 & 0 \\ \frac{e^{-\nu\pi i/2}}{W_n(z)} e^{-2n\varphi(z)} & 1 \end{pmatrix}, & z \in \Sigma_2 \cup \Sigma_3, \\ \begin{pmatrix} 0 & e^{\nu\pi i/2} W_n(x) \\ -\frac{e^{-\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix}, & z \in (-1, 0), \\ \begin{pmatrix} 0 & e^{-\nu\pi i/2} W_n(x) \\ -\frac{e^{\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix}, & z \in (0, 1), \\ \begin{pmatrix} 1 & e^{\nu\pi i/2} e^{2n\varphi(z)} W_n(z) \\ 0 & 1 \end{pmatrix}, & z \in (-\infty, -1), \\ \begin{pmatrix} 1 & e^{-\nu\pi i/2} e^{2n\varphi(z)} W_n(z) \\ 0 & 1 \end{pmatrix}, & z \in (1, \infty), \\ \begin{pmatrix} 1 & 0 \\ j_1(z) & 1 \end{pmatrix}, & z \in (0, i\rho), \\ \begin{pmatrix} 1 & 0 \\ j_2(z) & 1 \end{pmatrix}, & z \in (-i\rho, 0). \end{cases} \quad (3.27)$$

Here

$$j_1(z) = \frac{e^{\nu\pi i/2} e^{-2n\varphi_-(z)}}{W_{n,-}(z)} - \frac{e^{-\nu\pi i/2} e^{-2n\varphi_+(z)}}{W_{n,+}(z)}, \quad z \in (0, i\rho), \quad (3.28)$$

and

$$j_2(z) = -\frac{e^{\nu\pi i/2} e^{-2n\varphi_-(z)}}{W_{n,-}(z)} + \frac{e^{-\nu\pi i/2} e^{-2n\varphi_+(z)}}{W_{n,+}(z)}, \quad z \in (-i\rho, 0), \quad (3.29)$$

using the appropriate values of $\varphi_{\pm}(z)$ and $W_{n,\pm}(z)$ in each case. The imaginary axis is oriented upwards, and so for $z \in i\mathbb{R}$, we have that $\varphi_+(z)$ and $W_{n,+}(z)$ ($\varphi_-(z)$ and $W_{n,-}(z)$) denote the limiting value from the left (right) half-plane.

3) As $z \rightarrow \infty$,

$$S(z) = I + \mathcal{O}(1/z).$$

4) $S(z)$ remains bounded as $z \rightarrow 0$ with $\text{Im } z > 0$, and

$$S(z) = \begin{pmatrix} \mathcal{O}(z^\nu) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(z^\nu) & \mathcal{O}(z^{-\nu}) \end{pmatrix}, \quad \text{as } z \rightarrow 0 \text{ with } \text{Im } z < 0. \quad (3.30)$$

Note that as a consequence of the definition of $\varphi(z)$ in (3.18) and formula (3.20), $\text{Im } \varphi(x)$ is decreasing on $[-1, 1]$. Because of the Cauchy–Riemann equations, $\text{Re } \varphi(z) > 0$ as we move away from the interval.

We may and do assume that the lens is small enough such that $\text{Re } \varphi(z) > 0$ on the lips of the lens. Then it follows from (3.25) and (3.27) that the jump matrix J_S on the lips of the lens tends to I at an exponential rate as $n \rightarrow \infty$, if we stay away from the endpoints ± 1 . Also the jump matrix on $(-\infty, -1)$ and $(1, \infty)$ tends to the identity matrix. Thus for any $\delta > 0$, there is a constant $c > 0$ such that

$$J_S(z) = I + \mathcal{O}(e^{-cn}), \quad z \in \Sigma_S \setminus ([-1, 1] \cup [-i\rho, i\rho] \cup D(\pm 1, \delta)). \quad (3.31)$$

The condition (3.30) needs some explanation, since (3.23) and (3.26) at first sight lead to the behavior $S(z) = \begin{pmatrix} \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(1) & \mathcal{O}(z^{-\nu}) \end{pmatrix}$ as $z \rightarrow 0$ with $\text{Im } z < 0$. However, a cancellation takes place for the entries in the first column, as can be checked from the jump conditions for S , see (3.27) on the intervals $(-1, 0)$ and $(0, 1)$. Since S remains bounded as $z \rightarrow 0$ with $\text{Im } z > 0$, and

$$S_-(z) = S_+(z) \begin{pmatrix} 0 & \mathcal{O}(z^{-\nu}) \\ \mathcal{O}(z^\nu) & 0 \end{pmatrix}, \quad \text{as } z \rightarrow 0,$$

one finds (3.30).

3.6 Global parametrix

If we ignore the jump matrices in the RH problem for S except for the one on the interval $[-1, 1]$, we arrive at the following RH problem for a 2×2 matrix valued function N :

RH problem 3.8. 1) N is analytic in $\mathbb{C} \setminus [-1, 1]$.

2) N satisfies the jump conditions

$$N_+(x) = N_-(x) \begin{cases} \begin{pmatrix} 0 & e^{\nu\pi i/2} W_n(x) \\ -\frac{e^{-\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix}, & x \in (-1, 0), \\ \begin{pmatrix} 0 & e^{-\nu\pi i/2} W_n(x) \\ -\frac{e^{\nu\pi i/2}}{W_n(x)} & 0 \end{pmatrix}, & x \in (0, 1). \end{cases}$$

3) As $z \rightarrow \infty$,

$$N(z) = I + \mathcal{O}(1/z).$$

We solve the RH problem for N by means of two Szegő functions $D_{1,n}$ and D_2 , see also [15], that are associated with W_n and $e^{-\text{sgn}(x)\nu\pi i/2}$, respectively.

The first Szegő function $D_1 = D_{1,n}$ is defined by

$$D_{1,n}(z) = \exp \left(\frac{(z^2 - 1)^{1/2}}{2\pi} \int_{-1}^1 \frac{\log W_n(x)}{\sqrt{1-x^2}} \frac{dx}{z-x} \right), \quad (3.32)$$

which is defined and analytic for $z \in \mathbb{C} \setminus [-1, 1]$. It satisfies

$$D_{1,n+}(x)D_{1,n-}(x) = W_n(x), \quad x \in (-1, 1). \quad (3.33)$$

It follows from (3.32) that $D_{1,n}$ has no zeros in $\mathbb{C} \setminus [-1, 1]$ and

$$D_{\infty,n} := \lim_{z \rightarrow \infty} D_{1,n}(z) = \exp\left(\frac{1}{2\pi} \int_{-1}^1 \frac{\log W_n(x)}{\sqrt{1-x^2}} dx\right) \in (0, \infty). \quad (3.34)$$

In what follows we are not going to indicate the n -dependence in the notation for $D_{1,n}$ and $D_{\infty,n}$, since the dependence on n is only mildly. Indeed, because of (3.25) we have that $D_{1,n}$ tends to the Szegő function for the weight $|x|^{-1/2}$ with a rate as given in the following lemma.

Lemma 3.9. *We have*

$$D_{1,n}(z) = \left(\frac{z + (z^2 - 1)^{1/2}}{z}\right)^{1/4} \left(1 + \mathcal{O}\left(\frac{\log n}{n}\right)\right), \quad (3.35)$$

$$D_{\infty,n} = 2^{1/4} + \mathcal{O}\left(\frac{\log n}{n}\right), \quad (3.36)$$

as $n \rightarrow \infty$, with \mathcal{O} -term that is uniform for $z \in \mathbb{C} \setminus ([-1, 1] \cup D(0, \delta) \cup D(\pm 1, \delta))$ for any $\delta > 0$.

Proof. The Szegő function for $|x|^{-1/2}$ is

$$D(z; |x|^{-1/2}) = \exp\left(\frac{(z^2 - 1)^{1/2}}{2\pi} \int_{-1}^1 \frac{\log |x|^{-1/2}}{\sqrt{1-x^2}} \frac{dx}{z-x}\right) = \left(\frac{z + (z^2 - 1)^{1/2}}{z}\right)^{1/4}.$$

and so

$$\left(\frac{z + (z^2 - 1)^{1/2}}{z}\right)^{-1/4} D_{1,n}(z) = \exp\left(\frac{(z^2 - 1)^{1/2}}{2\pi} \int_{-1}^1 \frac{\log(|x|^{1/2} W_n(x))}{\sqrt{1-x^2}} \frac{dx}{z-x}\right). \quad (3.37)$$

Because of (3.25) there exist $c_0, c_1 > 0$

$$\left| |x|^{1/2} W_n(x) - 1 \right| \leq \frac{c_1}{n|x|} < \frac{1}{2}, \quad |x| \geq \frac{c_0}{n}.$$

Then also for some $c_2 > 0$,

$$\left| \log(|x|^{1/2} W_n(x)) \right| \leq \frac{c_2}{n|x|}, \quad |x| \geq \frac{c_0}{n}.$$

It follows that

$$\begin{aligned} \left| \int_{c_0/n}^1 \frac{\log(|x|^{1/2} W_n(x))}{\sqrt{1-x^2}} \frac{dx}{z-x} \right| &\leq \frac{c_2}{\text{dist}(z, [-1, 1])n} \int_{c_0/n}^1 \frac{1}{x\sqrt{1-x^2}} dx \\ &\leq \frac{c_3}{\text{dist}(z, [-1, 1])} \frac{\log n}{n} \end{aligned}$$

with a constant c_3 that is independent of n and z . By deforming the integration path into the complex plane in such a way that it stays at a certain distance from z , and applying similar estimates we find

$$\left| \int_{c_0/n}^1 \frac{\log(|x|^{1/2}W_n(x))}{\sqrt{1-x^2}} \frac{dx}{z-x} \right| \leq \frac{c_4 \log n}{|z| n} \quad (3.38)$$

with a constant that is independent of $z \in \mathbb{C} \setminus ([-1, 1] \cup D(0, \delta) \cup D(\pm 1, \delta))$. Similarly

$$\left| \int_{-1}^{-c_0/n} \frac{\log(|x|^{1/2}W_n(x))}{\sqrt{1-x^2}} \frac{dx}{z-x} \right| \leq \frac{c_5 \log n}{|z| n}. \quad (3.39)$$

Near $x = 0$ we use (3.10) and (3.22) to find a $c_6 > 0$ such that

$$c_6 |nx|^{1/2-\nu} \leq |x|^{1/2}W_n(x) \leq 1, \quad |x| \leq \frac{c_0}{n}.$$

The upper bound follows from the fact that $0 < K_\nu(s) \leq K_{1/2}(s)$ if $0 \leq \nu < 1/2$ and $s > 0$ and the explicit formula for $K_{1/2}(s)$ see [17, 10.37.1, 10.39.2]. Then

$$\left| \log(|x|^{1/2}W_n(x)) \right| \leq \log c_6 + \left(\frac{1}{2} - \nu\right) \log |nx|, \quad |x| \leq \frac{c_0}{n}$$

and

$$\left| \int_{-c_0/n}^{c_0/n} \frac{\log |x|^{1/2}W_n(x)}{\sqrt{1-x^2}} \frac{dx}{z-x} \right| \leq \frac{2}{|z|} \int_{-c_0/n}^{c_0/n} \left| \log c_6 + \left(\frac{1}{2} - \nu\right) \log |nx| \right| dx \leq \frac{c_7}{|z|} \frac{1}{n} \quad (3.40)$$

for some new constant $c_7 > 0$.

Combining the estimates (3.38), (3.39), and (3.40), we get

$$\left| \frac{(z^2 - 1)^{1/2}}{2\pi} \int_{-1}^1 \frac{\log(|x|^{1/2}W_n(x))}{\sqrt{1-x^2}} \frac{dx}{z-x} \right| = \mathcal{O}\left(\frac{\log n}{n}\right)$$

with a \mathcal{O} term that is uniform for $|z| > \delta$ $|z \pm 1| > \delta$, and so by (3.37)

$$\left(\frac{z + (z^2 - 1)^{1/2}}{z} \right)^{-1/4} D_{1,n}(z) = \exp\left(\mathcal{O}\left(\frac{\log n}{n}\right)\right) = 1 + \mathcal{O}\left(\frac{\log n}{n}\right)$$

as claimed in (3.35).

Since (3.35) is uniform for $|z| > \delta$, $|z \pm 1| > \delta$, we can let $z \rightarrow \infty$, and obtain (3.36). \square

The second Szegő function D_2 corresponds to the weight $e^{\pm\nu\pi i/2}$, and is defined as

$$D_2(z) = \left(\frac{\sqrt{z^2 - 1} - i}{\sqrt{z^2 - 1} + i} \right)^{\nu/4}, \quad z \in \mathbb{C} \setminus [-1, 1], \quad (3.41)$$

with the branch of the square root that is positive for real $z > 1$. It is not difficult to check that $z \mapsto w = D_2(z)$ is the conformal mapping from $\mathbb{C} \setminus [-1, 1]$ onto the sector $-\frac{\nu\pi}{4} < \arg w < \frac{\nu\pi}{4}$ that maps $z = 0+$ to $w = 0$, $z = 0-$ to $w = \infty$, $z = \pm 1$ to $e^{\mp \frac{\nu\pi}{4}}$ and $z = \infty$ to $w = 1$.

The Szegő function D_2 is related to the function ψ from (2.10).

Lemma 3.10. *We have*

$$\log D_2(z) = \begin{cases} -\frac{\nu\pi}{2}\psi(z) - \frac{\nu\pi i}{4}, & \operatorname{Re} z > 0, \operatorname{Im} z > 0, \\ \frac{\nu\pi}{2}\psi(z) - \frac{\nu\pi i}{4}, & \operatorname{Re} z > 0, \operatorname{Im} z < 0, \\ -\frac{\nu\pi}{2}\psi(z) + \frac{\nu\pi i}{4}, & \operatorname{Re} z < 0, \operatorname{Im} z > 0, \\ \frac{\nu\pi}{2}\psi(z) + \frac{\nu\pi i}{4}, & \operatorname{Re} z < 0, \operatorname{Im} z < 0. \end{cases} \quad (3.42)$$

Proof. This follows from (2.10) and (3.41) by straightforward calculation. \square

It follows from (3.42) that D_2 satisfies

$$D_{2+}(x)D_{2-}(x) = \begin{cases} e^{\nu\pi i/2}, & x \in (-1, 0), \\ e^{-\nu\pi i/2}, & x \in (0, 1), \end{cases} \quad (3.43)$$

and, since $\psi(z) \sim \frac{1}{\pi} \log(1/z)$ as $z \rightarrow 0$,

$$D_2(z) = \begin{cases} \mathcal{O}(z^{\nu/2}) & \text{as } z \rightarrow 0 \text{ with } \operatorname{Im} z > 0, \\ \mathcal{O}(z^{-\nu/2}) & \text{as } z \rightarrow 0 \text{ with } \operatorname{Im} z < 0. \end{cases} \quad (3.44)$$

Having D_1 and D_2 we seek N in the form

$$N(z) = D_\infty^{\sigma_3} N_0(z) (D_1(z)D_2(z))^{-\sigma_3}. \quad (3.45)$$

Then N satisfies the RH problem 3.8 if and only if N_0 satisfies the following standard RH problem:

RH problem 3.11. 1) N_0 is analytic in $\mathbb{C} \setminus [-1, 1]$.

2) N_0 satisfies the jump conditions

$$N_{0+}(x) = N_{0-}(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad x \in (-1, 1).$$

3) $N_0(z) = I + \mathcal{O}(1/z)$ as $z \rightarrow \infty$.

The RH problem for N_0 has the explicit solution (see for instance [5, Section 7.3]):

$$N_0(z) = \begin{pmatrix} \frac{\beta(z)+\beta(z)^{-1}}{2} & \frac{\beta(z)-\beta(z)^{-1}}{2i} \\ -\frac{\beta(z)-\beta(z)^{-1}}{2i} & \frac{\beta(z)+\beta(z)^{-1}}{2} \end{pmatrix}, \quad \text{with } \beta(z) = \left(\frac{z-1}{z+1} \right)^{1/4}, \quad (3.46)$$

for $z \in \mathbb{C} \setminus [-1, 1]$, and we take the branch of the fourth root that is analytic in $\mathbb{C} \setminus [-1, 1]$ and that is real and positive for $z > 1$. Note that we can also write

$$N_0(z) = \frac{1}{\sqrt{2}(z^2 - 1)^{1/4}} \begin{pmatrix} f(z)^{1/2} & if(z)^{-1/2} \\ -if(z)^{-1/2} & f(z)^{1/2} \end{pmatrix} \quad (3.47)$$

where

$$f(z) = z + (z^2 - 1)^{1/2} \quad (3.48)$$

is the conformal map from $\mathbb{C} \setminus [-1, 1]$ to the exterior of the unit disk.

3.7 Fifth transformation

Around the endpoints $z = \pm 1$ we build Airy parametrices P_{Ai} in the usual way. We take $\delta > 0$ sufficiently small, and P_{Ai} is defined and analytic in $D(\pm 1, \delta) \setminus \Sigma_S$ such that it has the same jumps as S on $\Sigma_S \cap D(\pm 1, \delta)$, and such that

$$P_{\text{Ai}}(z) = N(z)(1 + \mathcal{O}(n^{-1})), \quad \text{uniformly for } |z \pm 1| = \delta, \quad (3.49)$$

as $n \rightarrow \infty$. We refer the reader for instance to the monograph by Deift [5, §7.6] for details.

In the fifth transformation we put

$$Q = \begin{cases} SN^{-1}, & \text{outside the disks } D(\pm 1, \delta), \\ SP_{\text{Ai}}^{-1}, & \text{inside the disks.} \end{cases} \quad (3.50)$$

Then Q is defined and analytic outside of a contour consisting of Σ_S and two circles around ± 1 . The construction of the Airy parametrix is such that it has the same jump as S inside the circles. As a result Q is analytic inside the two disks. Also S and N have the same jump on $(-1, 1)$ and it follows that Q is analytic across $(-1, 1)$. Therefore Q is analytic in $\mathbb{C} \setminus \Sigma_Q$ where Σ_Q consists of two circles around ± 1 , the parts of $(-\infty, -1)$, Σ_j , $j = 1, \dots, 4$ and $(1, \infty)$ outside of these circles, and the segment $(-i\rho, i\rho)$ on the imaginary axis. See Figure 4.

From the RH problem 3.7 for S and (3.50) it then follows that Q solves the following RH problem.

RH problem 3.12. 1) $Q : \mathbb{C} \setminus \Sigma_Q \rightarrow \mathbb{C}^{2 \times 2}$ is analytic.

2) Q satisfies the jump condition $Q_+ = Q_- J_Q$ on Σ_Q where

$$J_Q(z) = \begin{cases} N(z)P_{\text{Ai}}^{-1}(z), & \text{for } z \text{ on the circles,} \\ N(z) \begin{pmatrix} 1 & 0 \\ j_1(z) & 1 \end{pmatrix} N^{-1}(z) & \text{for } z \in (0, i\rho), \\ N(z) \begin{pmatrix} 1 & 0 \\ j_2(z) & 1 \end{pmatrix} N^{-1}(z) & \text{for } z \in (-i\rho, 0), \\ N(z)J_S(z)N(z)^{-1}, & \text{elsewhere on } \Sigma_Q. \end{cases}$$

Here j_1 and j_2 are given by (3.28) and (3.29).

Figure 4: Contour Σ_Q

3) As $z \rightarrow \infty$,

$$Q(z) = I + \mathcal{O}(1/z).$$

4) $Q(z) = \mathcal{O}(1)$ as $z \rightarrow 0$.

In the behavior around 0 there is no longer a distinction between the upper and lower half planes, and Q remains bounded in all directions.

We note that

$$J_Q(z) = I + \mathcal{O}(n^{-1}), \quad \text{for } z \text{ on the circles} \quad (3.51)$$

because of the matching property (3.49). We also note that

$$J_Q(z) = I + \mathcal{O}(e^{-cn}), \quad \text{on } \Sigma_Q \setminus (\partial D(\pm 1, \delta) \cup [-i\rho, i\rho]) \quad (3.52)$$

because of (3.31), (3.45), and Lemma 3.9.

The jump matrix J_Q on the imaginary axis can be rewritten as (we use (3.45)):

$$J_Q(z) = D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 1 & 0 \\ j_{1,2}(z)(D_1(z)D_2(z))^2 & 1 \end{pmatrix} N_0^{-1}(z) D_\infty^{-\sigma_3}, \quad z \in (-i\rho, i\rho), \quad (3.53)$$

with j_1 on $(0, i\rho)$, and j_2 on $(-i\rho, 0)$.

The entry $j_{1,2}(z)(D_1(z)D_2(z))^2$ in (3.53) depends on n , and tends to 0 as $n \rightarrow \infty$ for every $z \in (-i\rho, 0) \cup (0, i\rho)$, but not in a uniform way. Hence, further analysis is needed in the next section. A similar situation is studied in [3, Section 5], where the jump on the imaginary axis has the same structure and approaches the identity matrix at a rate $1/\log(n)$ as $n \rightarrow \infty$. In that case no local parametrix near the origin is needed.

3.8 Local parametrix near $z = 0$

The construction of a local parametrix in a neighborhood of the origin follows the idea exposed in [13]. We take $\varepsilon > 0$ with

$$\varepsilon < \min\left(\frac{1}{2e}, \frac{\rho}{3}\right)$$

and we build a local parametrix P defined in a neighborhood $|z| < 3\varepsilon$ of 0. We use a cut-off function $\chi(z)$ on $i\mathbb{R}$ such that

- (a) $\chi : i\mathbb{R} \rightarrow \mathbb{R}$ is a C^∞ function,
- (b) $0 \leq \chi(z) \leq 1$ for all $z \in i\mathbb{R}$,
- (c) $\chi(z) \equiv 1$ for $z \in (-i\varepsilon, i\varepsilon)$,
- (d) $\chi(z) \equiv 0$ for $z \in (-i\infty, -2i\varepsilon) \cup (2i\varepsilon, i\infty)$.

Then we modify J_Q by multiplying the off-diagonal entry in the middle factor of (3.53) by $\chi(z)$, and in addition we use this as a jump matrix in the full imaginary axis. Thus

$$J_P(z) = D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 1 & 0 \\ j_{1,2}(z)(D_1(z)D_2(z))^2\chi(z) & 1 \end{pmatrix} N_0^{-1}(z) D_\infty^{-\sigma_3}, \quad z \in i\mathbb{R}, \quad (3.54)$$

with j_1 on $i\mathbb{R}^+$ and j_2 on $i\mathbb{R}^-$.

Then the RH problem for the local parametrix P at the origin is:

RH problem 3.13. 1) $P : \{z \in \mathbb{C} \mid -1 < \operatorname{Re} z < 1\} \setminus i\mathbb{R} \rightarrow \mathbb{C}^{2 \times 2}$ is analytic.

2) P satisfies the jump condition

$$P_+(z) = P_-(z)J_P(z), \quad z \in i\mathbb{R}, \quad (3.55)$$

where $J_P(z)$ is given by (3.54).

3) $P(z) = I + \mathcal{O}(\varepsilon_n)$ as $n \rightarrow \infty$ uniformly for $|z| = 3\varepsilon$ with ε_n given by (2.3).

Proposition 3.14. *The RH problem 3.13 has a solution for n large enough.*

The rest of this subsection is devoted to the proof of Proposition 3.14. It takes a number of steps and it is the most technical part of the paper.

3.8.1 RH problem for \widehat{P}

We introduce a matrix $\widehat{P}(z)$ in the following way:

$$P(z) = \begin{cases} D_\infty^{\sigma_3} N_0(z) \widehat{P}(z) N_0(z)^{-1} D_\infty^{-\sigma_3}, & \text{for } \operatorname{Im} z < 0, \\ D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \widehat{P}(z) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} N_0(z)^{-1} D_\infty^{-\sigma_3}, & \text{for } \operatorname{Im} z > 0. \end{cases} \quad (3.56)$$

The extra factors in (3.56) for $\operatorname{Im} z > 0$ are introduced in order to compensate the jumps of N_0 on $[-1, 1]$. Then P satisfies the jump condition (3.55) in the RH problem 3.13 if and only if $\widehat{P}_+ = \widehat{P}_- J_{\widehat{P}}$, where the jump is

$$J_{\widehat{P}}(z) = \begin{cases} \begin{pmatrix} 1 & -j_1(z)(D_1(z)D_2(z))^2\chi(z) \\ 0 & 1 \end{pmatrix}, & \text{for } z \in i\mathbb{R}^+, \\ \begin{pmatrix} 1 & 0 \\ j_2(z)(D_1(z)D_2(z))^2\chi(z) & 1 \end{pmatrix}, & \text{for } z \in i\mathbb{R}^-. \end{cases} \quad (3.57)$$

Note the difference in the triangularity structure. So, we look for \widehat{P} that solves the following RH problem:

RH problem 3.15. 1) $\widehat{P} : \mathbb{C} \setminus i\mathbb{R} \rightarrow \mathbb{C}^{2 \times 2}$ is analytic.

2) \widehat{P} satisfies the jump conditions

$$\widehat{P}_+(z) = \widehat{P}_-(z)J_{\widehat{P}}(z), \quad z \in i\mathbb{R}, \quad (3.58)$$

where $J_{\widehat{P}}(z)$ is given by (3.57).

3) $\widehat{P}(z) = I + \mathcal{O}(1/z)$ as $z \rightarrow \infty$.

Our aim is to show that the RH problem for \widehat{P} has a solution for n sufficiently large, and that this solution satisfies in addition

4) $\widehat{P}(z) = I + \mathcal{O}(\epsilon_n)$ as $n \rightarrow \infty$, uniformly for $|z| = 3\epsilon$.

Having \widehat{P} we define P by (3.56) in terms of \widehat{P} , and it will satisfy the requirements of the RH problem 3.13.

We prove the following result:

Lemma 3.16. *If $0 < \nu \leq 1/2$, then for n large enough there exists $\widehat{P}(z)$ that solves the RH problem 3.15, and as $n \rightarrow \infty$,*

$$|\widehat{P}_{11}(z) - 1| = \mathcal{O}\left(n^{-1/2}(\log n)^{-2\nu-1/2}\right), \quad |\widehat{P}_{21}(z)| = \mathcal{O}\left(n^{\nu-1/2}(\log n)^{-\nu-1/2}\right),$$

in $\mathbb{C} \setminus [-2i\epsilon, 0]$, and

$$|\widehat{P}_{12}(z)| = \mathcal{O}\left(n^{-\nu-1/2}(\log n)^{-\nu-1/2}\right), \quad |\widehat{P}_{22}(z) - 1| = \mathcal{O}\left(n^{-1/2}(\log n)^{-2\nu-1/2}\right),$$

in $\mathbb{C} \setminus [0, 2i\epsilon]$.

Remark 3.17. It follows from Lemma 3.16 that $\widehat{P}(z) = I + \mathcal{O}(\epsilon_n)$ as $n \rightarrow \infty$, uniformly for $|z| = 3\epsilon$, and because of (3.56), the same holds for $P(z)$.

In the proof of this lemma we will need the following steps:

1. We write the jump conditions for $\widehat{P}(z)$ componentwise, and in terms of two integral operators K_1 and K_2 .
2. We estimate the operator norms $\|K_1\|$ and $\|K_2\|$ as $n \rightarrow \infty$. This requires estimates for the functions $j_1(z)$, $j_2(z)$, $D_1(z)$ and $D_2(z)$, which are uniform as $n \rightarrow \infty$ for y in a fixed interval around the origin on the imaginary axis.
3. We show that the operators $I - K_2K_1$ and $I - K_1K_2$ are invertible for n large enough, and this gives the existence and asymptotics of \widehat{P} .

Finally, the estimates for $\widehat{P}(z)$ are used to prove that the matrix $R(z)$, which will be defined in Section 3.9 and which solves the Riemann–Hilbert problem 3.24, is close to the identity matrix as $n \rightarrow \infty$.

3.8.2 Integral operators

Let us write

$$\begin{aligned}\eta_1(z) &= -j_1(z)(D_1(z)D_2(z))^2\chi(z), & z \in i\mathbb{R}^+, \\ \eta_2(z) &= j_2(z)(D_1(z)D_2(z))^2\chi(z), & z \in i\mathbb{R}^-. \end{aligned} \quad (3.59)$$

These functions depend on n , since j_1 , j_2 and D_1 depend on n . Note, however, that D_2 and χ do not depend on n .

The jump condition (3.57)-(3.58) yields that for $j = 1, 2$,

$$\begin{aligned}\widehat{P}_{j1+}(z) &= \begin{cases} \widehat{P}_{j1-}(z), & \text{for } z \in i\mathbb{R}^+, \\ \widehat{P}_{j1-}(z) + \eta_2(z)\widehat{P}_{j2-}(z), & \text{for } z \in i\mathbb{R}^-, \end{cases} \\ \widehat{P}_{j2+}(z) &= \begin{cases} \widehat{P}_{j2-}(z) + \eta_1(z)\widehat{P}_{j1-}(z), & \text{for } z \in i\mathbb{R}^+, \\ \widehat{P}_{j2-}(z), & \text{for } z \in i\mathbb{R}^-. \end{cases} \end{aligned} \quad (3.60)$$

Since $\chi(z) = 0$ for $|z| \geq 2\varepsilon$, we find that \widehat{P}_{j1} is analytic in $\mathbb{C} \setminus [-2i\varepsilon, 0]$, and \widehat{P}_{j2} is analytic in $\mathbb{C} \setminus [0, 2i\varepsilon]$. Then by the Sokhotski-Plemelj formula and the asymptotic condition $\widehat{P}(z) \rightarrow I$ as $z \rightarrow \infty$, we get

$$\begin{aligned}\widehat{P}_{11}(z) &= 1 + \frac{1}{2\pi i} \int_{-2i\varepsilon}^0 \frac{\eta_2(s)\widehat{P}_{12}(s)}{s-z} ds, & \widehat{P}_{12}(z) &= \frac{1}{2\pi i} \int_0^{2i\varepsilon} \frac{\eta_1(s)\widehat{P}_{11}(s)}{s-z} ds, \\ \widehat{P}_{21}(z) &= \frac{1}{2\pi i} \int_{-2i\varepsilon}^0 \frac{\eta_2(s)\widehat{P}_{22}(s)}{s-z} ds, & \widehat{P}_{22}(z) &= 1 + \frac{1}{2\pi i} \int_0^{2i\varepsilon} \frac{\eta_1(s)\widehat{P}_{21}(s)}{s-z} ds. \end{aligned} \quad (3.61)$$

We can write the equations in operator form if we introduce two operators

$$K_1 : L^2([0, 2i\varepsilon]) \rightarrow L^2([-2i\varepsilon, 0]) \quad \text{and} \quad K_2 : L^2([-2i\varepsilon, 0]) \rightarrow L^2([0, 2i\varepsilon])$$

by

$$(K_1 f)(z) = \frac{1}{2\pi i} \int_0^{2i\varepsilon} \frac{\eta_1(s)f(s)}{s-z} ds, \quad f \in L^2([0, 2i\varepsilon]), \quad (3.62)$$

$$(K_2 g)(z) = \frac{1}{2\pi i} \int_{-2i\varepsilon}^0 \frac{\eta_2(s)g(s)}{s-z} ds, \quad g \in L^2([-2i\varepsilon, 0]). \quad (3.63)$$

Then $f_1 = \widehat{P}_{11}$, $g_1 = \widehat{P}_{12}$ should solve

$$f_1 = 1 + K_2 g_1, \quad g_1 = K_1 f_1 \quad (3.64)$$

and $f_2 = \widehat{P}_{21}$, $g_2 = \widehat{P}_{22}$ should solve

$$f_2 = K_2 g_2, \quad g_2 = 1 + K_1 f_2. \quad (3.65)$$

Both K_1 and K_2 are integral operators between Hilbert spaces with operator norms

$$\begin{aligned}\|K_1\|^2 &= \int_{-2i\varepsilon}^0 \int_0^{2i\varepsilon} \frac{|\eta_1(s)|^2}{|s-t|^2} |ds| |dt|, \\ \|K_2\|^2 &= \int_0^{2i\varepsilon} \int_{-2i\varepsilon}^0 \frac{|\eta_2(s)|^2}{|s-t|^2} |ds| |dt|. \end{aligned}$$

The t -integrals can be done explicitly. This leads to the estimates (we also change to a real integration variable by putting $s = \pm iy$)

$$\|K_1\| \leq \left(\int_0^{2\varepsilon} \frac{|\eta_1(iy)|^2}{y} dy \right)^{1/2}, \quad \|K_2\| \leq \left(\int_0^{2\varepsilon} \frac{|\eta_2(-iy)|^2}{y} dy \right)^{1/2}. \quad (3.66)$$

The next step is to show that both integrals are finite (so that K_1 and K_2 are well-defined bounded operators) and that $\|K_1 K_2\|$ and $\|K_2 K_1\|$ tend to 0 as $n \rightarrow \infty$. To this end, we need to control the functions η_1 and η_2 , defined in (3.59).

3.8.3 The functions $\eta_1(z)$ and $\eta_2(z)$

The functions η_1 and η_2 are defined in terms of j_1 , j_2 , D_1 and D_2 , see (3.59). In this section we obtain estimates for all these functions for large n .

First we write the functions $j_1(z)$ and $j_2(z)$ in terms of Bessel functions. Because of the property $K_\nu(\bar{z}) = \overline{K_\nu(z)}$ for real ν , see [17, §10.34.7], if we consider the positive imaginary axis and we write $z = iy$, with $y > 0$, then the function W_n (recall (3.24)) can be written as

$$W_{n,\pm}(iy) = \sqrt{2n} K_\nu(\mp n\pi iy) e^{\mp n\pi iy}, \quad (3.67)$$

so $W_{n,+}(iy) = \overline{W_{n,-}(iy)}$. Similarly, on the negative imaginary axis,

$$W_{n,\pm}(-iy) = \sqrt{2n} K_\nu(\pm n\pi iy) e^{\mp n\pi iy}, \quad (3.68)$$

so again $W_{n,+}(-iy) = \overline{W_{n,-}(-iy)}$. Additionally, we have

$$\begin{aligned} |W_{n,-}(iy)|^2 &= 2n |K_\nu(n\pi iy)|^2 = \frac{n\pi^2}{2} |H_\nu^{(2)}(n\pi y)|^2 = \frac{n\pi^2}{2} [J_\nu(n\pi y)^2 + Y_\nu(n\pi y)^2], \\ |W_{n,-}(-iy)|^2 &= 2n |K_\nu(-n\pi iy)|^2 = \frac{n\pi^2}{2} |H_\nu^{(1)}(n\pi y)|^2 = \frac{n\pi^2}{2} [J_\nu(n\pi y)^2 + Y_\nu(n\pi y)^2], \end{aligned} \quad (3.69)$$

in terms of Hankel functions, see [17, §10.27.8]. We have the following auxiliary result:

Lemma 3.18. *For $y > 0$, the functions $j_1(iy)$ and $j_2(-iy)$ can be written as follows:*

$$\begin{aligned} |j_1(iy)| &= \frac{2e^{-2n \operatorname{Re} \varphi_-(iy)}}{\sqrt{2n\pi}} \frac{|J_\nu(n\pi y) \cos \nu\pi - Y_\nu(n\pi y) \sin \nu\pi|}{J_\nu^2(n\pi y) + Y_\nu^2(n\pi y)}, \\ |j_2(-iy)| &= \frac{2e^{-2n \operatorname{Re} \varphi_-(-iy)}}{\sqrt{2n\pi}} \frac{|J_\nu(n\pi y)|}{J_\nu^2(n\pi y) + Y_\nu^2(n\pi y)}. \end{aligned}$$

Proof. It follows from (3.28) that j_1 can be written as

$$j_1(iy) = \frac{e^{-2n\varphi_-(iy) - n\pi iy}}{\overline{W_{n,-}(iy)} W_{n,+}(iy)} \left[e^{\frac{\nu\pi i}{2} + n\pi iy} W_{n,+}(iy) - e^{-\frac{\nu\pi i}{2} - n\pi iy} W_{n,-}(iy) \right],$$

and because of $\varphi_-(z) = \varphi_+(z) - \pi z$ on the imaginary axis, and the fact that $W_{n,+}(iy) = \overline{W_{n,-}(iy)}$, the two terms on the right hand side are complex conjugates, so

$$j_1(iy) = \frac{-2ie^{-2n\varphi_-(iy)-n\pi iy}}{|W_{n,-}(iy)|^2} \operatorname{Im} \left[e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(iy) \right]. \quad (3.70)$$

Using the formula

$$K_\nu(z) = -\frac{\pi i}{2} e^{-\frac{\nu\pi i}{2}} H_\nu^{(2)}(ze^{-\frac{\pi i}{2}}), \quad -\frac{\pi}{2} < \arg z \leq \pi,$$

in terms of Hankel functions, see [17, §10.27.8] and (3.67) we observe that

$$e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(iy) = e^{-\frac{\nu\pi i}{2}} \sqrt{2n} K_\nu(n\pi iy) = -\frac{\sqrt{2n\pi} e^{-\nu\pi i}}{2} (J_\nu(n\pi y) - iY_\nu(n\pi y)).$$

Hence, on the positive imaginary axis,

$$\operatorname{Im} \left[e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(iy) \right] = -\frac{\sqrt{2n\pi}}{2} (J_\nu(n\pi y) \cos \nu\pi - Y_\nu(n\pi y) \sin \nu\pi).$$

Using (3.70) and (3.69), this proves the first formula. Similarly, for $y > 0$,

$$j_2(-iy) = \frac{2ie^{-2n\varphi_-(-iy)-n\pi iy}}{|W_{n,-}(-iy)|^2} \operatorname{Im} \left[e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(-iy) \right]. \quad (3.71)$$

In this case, we use

$$K_\nu(z) = \frac{\pi i}{2} e^{\frac{\nu\pi i}{2}} H_\nu^{(1)}(ze^{\frac{\pi i}{2}}), \quad -\pi < \arg z \leq \frac{\pi}{2},$$

see [17, 10.27.8], and (3.68) to obtain

$$e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(-iy) = e^{-\nu\pi i/2} \sqrt{2n} K_\nu(-n\pi iy) = \frac{\sqrt{2n\pi} i}{2} (J_\nu(n\pi y) + iY_\nu(n\pi y)),$$

so

$$\operatorname{Im} \left[e^{-\frac{\nu\pi i}{2}-n\pi iy} W_{n,-}(-iy) \right] = \frac{\sqrt{2n\pi}}{2} J_\nu(n\pi y).$$

We use (3.71) and (3.69), and this completes the proof. \square

Next, we will obtain estimates of the previous functions j_1 and j_2 for large n .

Lemma 3.19. *For $0 < \nu \leq 1/2$ there exist constants $C_\nu, C'_\nu > 0$ such that for all $s > 0$ we have*

$$\begin{aligned} \frac{|J_\nu(s) \cos \nu\pi - Y_\nu(s) \sin \nu\pi|}{J_\nu(s)^2 + Y_\nu(s)^2} &\leq C_\nu \frac{s^\nu(1+s^{1-2\nu})}{1+s^{1/2-\nu}}, \\ \frac{|J_\nu(s)|}{J_\nu(s)^2 + Y_\nu(s)^2} &\leq C'_\nu \frac{s^{3\nu}(1+s^{1-2\nu})}{1+s^{1/2+\nu}}. \end{aligned}$$

Proof. For the proof, we consider the following expansions: as $s \rightarrow 0^+$,

$$J_\nu(s) = \frac{s^\nu}{2^\nu \Gamma(\nu+1)} (1 + \mathcal{O}(s^{-1})), \quad \nu \neq -1, -2, \dots \quad (3.72)$$

and for $\nu < 1$ we have

$$Y_\nu(s) = -\frac{\Gamma(\nu)}{\pi} \left(\frac{s}{2}\right)^{-\nu} + \mathcal{O}(s^\nu). \quad (3.73)$$

As $s \rightarrow \infty$, we have

$$J_\nu(s) = \left(\frac{2}{\pi s}\right)^{1/2} \cos \omega (1 + \mathcal{O}(s^{-1})), \quad Y_\nu(s) = \left(\frac{2}{\pi s}\right)^{1/2} \sin \omega (1 + \mathcal{O}(s^{-1})), \quad (3.74)$$

where $\omega = s - \frac{\nu\pi}{2} - \frac{\pi}{4}$. See for instance [17, formulas 10.7.3–4, 10.17.3–4].

From this, it follows that

$$\begin{aligned} J_\nu(s)^2 + Y_\nu(s)^2 &= \frac{\Gamma(\nu)^2}{\pi^2} \left(\frac{s}{2}\right)^{-2\nu} + \mathcal{O}(1), & s \rightarrow 0, \\ J_\nu(s)^2 + Y_\nu(s)^2 &= \frac{2}{\pi s} + \mathcal{O}(s^{-2}), & s \rightarrow \infty. \end{aligned} \quad (3.75)$$

From (3.75), we claim that there exist two constants $C_{1,\nu}, C_{2,\nu} > 0$ such that

$$C_{1,\nu} \frac{s^{-2\nu}}{1 + s^{1-2\nu}} \leq J_\nu(s)^2 + Y_\nu(s)^2 \leq C_{2,\nu} \frac{s^{-2\nu}}{1 + s^{1-2\nu}}, \quad s > 0.$$

Using a similar argument, we have

$$|J_\nu(s)| \leq C_{3,\nu} \frac{s^\nu}{1 + s^{1/2-\nu}},$$

and also

$$|J_\nu(s) \cos \nu\pi - Y_\nu(s) \sin \nu\pi| \leq C_{4,\nu} \frac{s^{-\nu}}{1 + s^{1/2-\nu}},$$

and putting all the estimates together we get the bounds in the lemma. \square

As a consequence of Lemma 3.18 and Lemma 3.19 we obtain the following bounds for j_1 and j_2 for $y > 0$:

$$\begin{aligned} |j_1(iy)| &\leq C_\nu \frac{2e^{-2n \operatorname{Re} \varphi_-(iy)}}{\sqrt{2n\pi}} \frac{(n\pi y)^\nu (1 + (n\pi y)^{1-2\nu})}{1 + (n\pi y)^{1/2-\nu}}, \\ |j_2(-iy)| &\leq C'_\nu \frac{2e^{-2n \operatorname{Re} \varphi_-(-iy)}}{\sqrt{2n\pi}} \frac{(n\pi y)^{3\nu} (1 + (n\pi y)^{1-2\nu})}{1 + (n\pi y)^{1/2+\nu}}. \end{aligned} \quad (3.76)$$

Next, we need an estimate for $D_1(z)$ (see formula (3.32)), with $z = iy$, $y \in [-\rho, \rho]$ where we recall that $\pm i\rho$ is the intersection of the lens with the imaginary axis.

Lemma 3.20. For $0 < \nu \leq 1/2$, there exists a constant C_ν such that for all sufficiently large n ,

$$|D_1(iy)|^2 \leq C_\nu \frac{n^{1/2-\nu}|y|^{-\nu}}{1 + (n|y|)^{1/2-\nu}}, \quad y \in [-\rho, \rho]. \quad (3.77)$$

Proof. We write first $z = iy$ with $y > 0$ in (3.32) and use the parity of the function W_n to get the following expression:

$$D_1(iy) = \exp\left(\frac{y(y^2 + 1)^{1/2}}{2\pi} \int_0^1 \frac{\log W_n(x)}{\sqrt{1-x^2}} \frac{dx}{x^2 + y^2}\right). \quad (3.78)$$

Using the asymptotic expansions (3.72), (3.73) and (3.74), we claim that there exist two constants C_1 and C_2 , depending on ν , such that $W_n(x)$ satisfies

$$W_n(x) \leq C_1|x|^{-1/2}, \quad |n\pi x| \geq 1,$$

and

$$W_n(x) \leq C_2n^{1/2-\nu}|x|^{-\nu}, \quad |n\pi x| \leq 1.$$

Since $\nu \leq 1/2$, both bounds hold uniformly for $n\pi x > 0$. Since the integrand in (3.78) is a real function, we can bound $D_1(iy)$ from above by another Szegő function:

$$D_1(iy)^2 \leq D(iy; C_1|\pi x|^{-1/2})^2 = C_1\pi^{-1/2}D(iy; |x|^{-1/2})^2.$$

This last Szegő function is explicit, since for a general exponent $\alpha > -1$ we have

$$D(z; |x|^\alpha) = \left(\frac{z}{z + \sqrt{z^2 - 1}}\right)^{\alpha/2}. \quad (3.79)$$

As a consequence, substituting $z = iy$ with $y \in [-\rho, \rho]$, and $\alpha = -1/2$,

$$D_1(iy)^2 \leq C_1(ny)^{-1/2}(y + \sqrt{y^2 + 1})^{1/2} \leq C_1\left(\rho + \sqrt{\rho^2 + 1}\right)^{1/2}(ny)^{-1/2},$$

and by the same argument with $\alpha = -\nu$,

$$D_1(iy)^2 \leq C_2n^{1/2-\nu}y^{-\nu}(y + \sqrt{y^2 + 1})^\nu \leq C_2\left(\rho + \sqrt{\rho^2 + 1}\right)^\nu n^{1/2-\nu}y^{-\nu}.$$

The bound in the lemma follows for $y > 0$ from these two estimates, for some constant C_ν . Finally, from the definition of D_1 , see (3.32), we have that if $y < 0$, then $D_1(iy) = \overline{D_1(-iy)}$, so the modulus is equal and the bound holds also in this case. \square

Now we write together all the estimates computed before to obtain bounds for the functions η_1 and η_2 defined in (3.59).

Lemma 3.21. For $0 < \nu \leq 1/2$, there exist constants $C_\nu, C'_\nu > 0$ such that for n large enough and $y \in [0, \rho]$, we have the bounds

$$|\eta_1(iy)| \leq |j_1(iy)(D_1(iy)D_2(iy))^2| \leq C_\nu y^\nu e^{-2n \operatorname{Re} \varphi_-(iy)}, \quad (3.80)$$

$$|\eta_2(-iy)| \leq |j_2(-iy)(D_1(-iy)D_2(-iy))^2| \leq C'_\nu (n^{2\nu}y^\nu + ny^{1-\nu}) e^{-2n \operatorname{Re} \varphi_-(-iy)}. \quad (3.81)$$

Proof. We collect the results on D_1 (see formula (3.77)), D_2 (we use the fact that this function does not depend on n and formula (3.44)), j_1 and j_2 (formula (3.76)). Then for some constant $C_{1,\nu}$ we simplify the bound to

$$|\eta_1(iy)| \leq C_{1,\nu} y^\nu \frac{1 + (ny)^{1-2\nu}}{(1 + (ny)^{1/2-\nu})^2} e^{-2n \operatorname{Re} \varphi_-(iy)} \leq C_\nu y^\nu e^{-2n \operatorname{Re} \varphi_-(iy)}.$$

Also,

$$\begin{aligned} |\eta_2(-iy)| &\leq C_{2,\nu} n^{2\nu} y^\nu \frac{1 + (ny)^{1-2\nu}}{(1 + (ny)^{1/2+\nu})(1 + (ny)^{1/2-\nu})} e^{-2n \operatorname{Re} \varphi_-(-iy)} \\ &\leq C'_\nu n^{2\nu} y^\nu (1 + (ny)^{1-2\nu}) e^{-2n \operatorname{Re} \varphi_-(-iy)}, \end{aligned}$$

and the result follows. \square

3.8.4 Estimates for $\|K_1\|$ and $\|K_2\|$ as $n \rightarrow \infty$

In order to estimate the norms of K_1 and K_2 we need the $\|\cdot\|_2$ norm of η_1 and η_2 , see formula (3.66). For this we use the estimate in Lemma 3.21 and the following bound on $\varphi(z)$:

Lemma 3.22. *For every $s \in i\mathbb{R}$ we have*

$$\begin{aligned} \operatorname{Re} \varphi_+(s) = \operatorname{Re} \varphi_-(s) &= -|s| \log |s| + |s| \log(1 + \sqrt{1 + s^2}) + \log(|s| + \sqrt{1 + s^2}) \\ &\geq |s| \log \frac{1}{|s|}. \end{aligned} \tag{3.82}$$

Proof. We consider $\operatorname{Re} \varphi_-(s)$ with $s \in i\mathbb{R}_+$. The other cases follow by symmetry. Let $x \in (0, 1)$. Then by (3.15) and (3.20),

$$\varphi_\pm(x) = \pm \pi i \int_x^1 \psi(t) dt,$$

and so $\varphi'_+(x) = -\pi i \psi(x)$. By analytic continuation we find

$$\varphi'(z) = -\pi i \psi(z), \quad \operatorname{Re} z > 0, \operatorname{Im} z > 0.$$

Then

$$\varphi_-(s) = \varphi_+(x) + \int_x^s \varphi'(z) dz = \varphi_+(x) - \pi i \int_x^s \psi(z) dz.$$

Since $\varphi_+(x)$ is purely imaginary, we obtain by taking the real part and letting $x \rightarrow 0+$,

$$\operatorname{Re} \varphi_-(s) = \operatorname{Im} \pi \int_0^s \psi(z) dz = \operatorname{Im} \int_0^s \log \left(\frac{1 + (1 - z^2)^{1/2}}{z} \right) dz,$$

where we used (2.10) for ψ . The integral can be evaluated explicitly and it gives (3.82). \square

Without loss of generality we assume in what follows that ρ is small enough so that $|s| \log \frac{1}{|s|} > 0$ for $s \in (-i\rho, i\rho)$.

In order to estimate integrals involving the functions $\varphi_{\pm}(z)$, we use (3.82), together with the following technical lemma.

Lemma 3.23. *For any $\alpha > -1$, there exists a constant $C = C_{\alpha}$ such that for n large enough*

$$\int_0^{1/e} y^{\alpha} e^{-4ny \log \frac{1}{y}} dy \leq C(n \log n)^{-\alpha-1}. \quad (3.83)$$

Proof. We split the integral into two parts and we estimate

$$\begin{aligned} \int_0^{1/e} y^{\alpha} e^{-4ny \log \frac{1}{y}} dy &= \int_0^{1/\sqrt{n}} y^{\alpha} e^{-4ny \log \frac{1}{y}} dy + \int_{1/\sqrt{n}}^{1/e} y^{\alpha} e^{-4ny \log \frac{1}{y}} dy \\ &\leq \int_0^{1/\sqrt{n}} y^{\alpha} e^{-4yn \log n} dy + \int_{1/\sqrt{n}}^{1/e} y^{\alpha} e^{-2\sqrt{n} \log n} dy. \end{aligned} \quad (3.84)$$

where for the second integral we used that $-y \log \frac{1}{y}$ is decreasing on $[0, \frac{1}{e}]$ and so $-y \log \frac{1}{y} \leq \frac{1}{\sqrt{n}} \log \sqrt{n}$ for $y \in [\frac{1}{\sqrt{n}}, \frac{1}{e}]$. The first integral of (3.84) is estimated by extending the integral to $+\infty$ and the result is that it is $\mathcal{O}((n \log n)^{-\alpha-1})$ as $n \rightarrow \infty$. The second integral in (3.84) is $\mathcal{O}(e^{-c\sqrt{n}})$ as $n \rightarrow \infty$. This gives the result. \square

Combining the estimates in (3.80), (3.81), (3.82) and (3.83) we obtain, whenever $2\varepsilon < \frac{1}{e}$,

$$\int_0^{2\varepsilon} |\eta_1(iy)|^2 dy = \mathcal{O}(n^{-2\nu-1}(\log n)^{-2\nu-1}), \quad \int_0^{2\varepsilon} \frac{|\eta_1(iy)|^2}{y} dy = \mathcal{O}(n^{-2\nu}(\log n)^{-2\nu}), \quad (3.85)$$

and

$$\int_0^{2\varepsilon} |\eta_2(-iy)|^2 dy = \mathcal{O}(n^{2\nu-1}(\log n)^{-2\nu-1}), \quad \int_0^{2\varepsilon} \frac{|\eta_2(-iy)|^2}{y} dy = \mathcal{O}(n^{2\nu}(\log n)^{-2\nu}), \quad (3.86)$$

as $n \rightarrow \infty$. To obtain (3.86) one has to consider the three different integrals coming from square of the factor $n^{2\nu}y^{\nu} + ny^{1-\nu}$ in (3.80)–(3.81), and retain the largest one.

Hence, using (3.66) and (3.85)–(3.86) we have the bounds

$$\begin{aligned} \|K_1\| &\leq \left(\int_0^{2\varepsilon} \frac{|\eta_1(iy)|^2}{y} dy \right)^{1/2} = \mathcal{O}(n^{-\nu}(\log n)^{-\nu}), \\ \|K_2\| &\leq \left(\int_0^{2\varepsilon} \frac{|\eta_2(-iy)|^2}{y} dy \right)^{1/2} = \mathcal{O}(n^{\nu}(\log n)^{-\nu}). \end{aligned} \quad (3.87)$$

Thus K_1 and K_2 are bounded operators between the Hilbert spaces $L^2([0, 2i\varepsilon])$ and $L^2([-2i\varepsilon, 0])$. In addition from (3.87), we get

$$\|K_1 K_2\| \leq \|K_1\| \|K_2\| = \mathcal{O}((\log n)^{-2\nu}), \quad n \rightarrow \infty, \quad (3.88)$$

and similarly

$$\|K_2K_1\| = \mathcal{O}((\log n)^{-2\nu}), \quad n \rightarrow \infty. \quad (3.89)$$

3.8.5 Proof of Lemma 3.16

Proof. It follows from (3.88) and (3.89) that the operators $I - K_2K_1$ and $I - K_1K_2$ are invertible for n large enough, and then we can solve the equations (3.64) and (3.65). Thus we define the entries of the matrix \widehat{P} as follows:

$$\widehat{P}_{11} = (I - K_2K_1)^{-1}1, \quad \widehat{P}_{12} = K_1\widehat{P}_{11} \quad (3.90)$$

$$\widehat{P}_{21} = K_2\widehat{P}_{22}, \quad \widehat{P}_{22} = (I - K_1K_2)^{-1}1. \quad (3.91)$$

In (3.90) and (3.91) we use 1 to denote the identically-one function in $L^2([0, 2i\varepsilon])$ and $L^2([-2i\varepsilon, 0])$, respectively. Then (3.64) and (3.65) hold true, which means that the equations in (3.61) hold. This then also means that the jump condition (3.58) in the RH problem 3.15 is satisfied.

The equations (3.61) allow us to give estimates on $\widehat{P}(z)$. First of all we obtain from (3.88)-(3.89), (3.90), and (3.91) that

$$\|\widehat{P}_{11}\|_{L^2([0, 2i\varepsilon])} = \mathcal{O}(1), \quad \|\widehat{P}_{22}\|_{L^2([-2i\varepsilon, 0])} = \mathcal{O}(1), \quad (3.92)$$

and then by (3.87)

$$\|\widehat{P}_{12}\|_{L^2([-2i\varepsilon, 0])} \leq \|K_1\| \|\widehat{P}_{11}\|_{L^2([0, 2i\varepsilon])} = \mathcal{O}(n^{-\nu}(\log n)^{-\nu}), \quad (3.93)$$

$$\|\widehat{P}_{21}\|_{L^2([0, 2i\varepsilon])} \leq \|K_2\| \|\widehat{P}_{22}\|_{L^2([-2i\varepsilon, 0])} = \mathcal{O}(n^\nu(\log n)^{-\nu}). \quad (3.94)$$

For pointwise estimates we use the distances

$$d_+(z) = \text{dist}(z, [0, 2i\varepsilon]), \quad d_-(z) = \text{dist}(z, [-2i\varepsilon, 0]).$$

Then by the first equation in (3.61), we get for $z \in \mathbb{C} \setminus [-2i\varepsilon, 0]$,

$$|\widehat{P}_{11}(z) - 1| \leq \frac{1}{2\pi d_-(z)} \left| \int_0^{2i\varepsilon} \eta_2(s) \widehat{P}_{12}(s) ds \right| \leq \frac{1}{2\pi d_-(z)} \|\eta_2\|_2 \|\widehat{P}_{12}\|_2$$

where we used the Cauchy-Schwarz inequality, and $\|\cdot\|_2$ is the L^2 norm on $[-2i\varepsilon, 0]$. Thus by (3.86) and (3.93),

$$|\widehat{P}_{11}(z) - 1| = \frac{1}{d_-(z)} \mathcal{O}\left(n^{-1/2}(\log n)^{-2\nu-1/2}\right), \quad (3.95)$$

as $n \rightarrow \infty$, uniformly for $z \in \mathbb{C} \setminus [-2i\varepsilon, 0]$. Using similar arguments, we obtain

$$|\widehat{P}_{12}(z)| = \frac{1}{d_+(z)} \mathcal{O}\left(n^{-\nu-1/2}(\log n)^{-\nu-1/2}\right), \quad (3.96)$$

$$|\widehat{P}_{21}(z)| = \frac{1}{d_-(z)} \mathcal{O}\left(n^{\nu-1/2}(\log n)^{-\nu-1/2}\right), \quad (3.97)$$

$$|\widehat{P}_{22}(z) - 1| = \frac{1}{d_+(z)} \mathcal{O}\left(n^{-1/2}(\log n)^{-2\nu-1/2}\right), \quad (3.98)$$

Figure 5: Contour Σ_R

as $n \rightarrow \infty$, and the \mathcal{O} terms are uniform in z . Observe that all \mathcal{O} terms tend to 0 as $n \rightarrow \infty$, since $\nu \leq 1/2$.

It follows from (3.95)–(3.98) that $\widehat{P}(z) = I + \mathcal{O}(z^{-1})$ as $z \rightarrow \infty$ and therefore \widehat{P} satisfies the RH problem 3.15. For $|z| = 3\epsilon$ we have $d_{\pm}(z) \geq \epsilon$. From (3.95)–(3.98) we then immediately find that the estimates in Lemma 3.16 hold, and the lemma is proved. \square

This also completes the proof of Proposition 3.14.

3.9 Final transformation

Having P as in Proposition 3.14 we define the final transformation $Q \mapsto R$ as

$$R(z) = \begin{cases} Q(z), & \text{for } |z| > 3\epsilon, \\ Q(z)P(z)^{-1}, & \text{for } |z| < 3\epsilon. \end{cases} \quad (3.99)$$

Recall that Q is the solution of the RH problem 3.12.

Then R has jumps on a contour Σ_R that consists of $\Sigma_Q \setminus (-i\epsilon, i\epsilon)$ together with the circle of radius 3ϵ around 0, see Figure 5. Note that the jumps of P and Q coincide on $(-i\epsilon, i\epsilon)$, so that R has an analytic continuation across that interval.

From RH problem 3.12 and the definition (3.99) it follows that R satisfies the following RH problem.

RH problem 3.24. 1) $R : \mathbb{C} \setminus \Sigma_R \rightarrow \mathbb{C}^{2 \times 2}$ is analytic.

2) R satisfies the jump condition $R_+ = R_- J_R$ on Σ_R where

$$J_R(z) = \begin{cases} J_Q(z) & \text{for } z \in \Sigma_R \text{ with } |z| > 3\epsilon, \\ P(z)^{-1} & \text{for } |z| = 3\epsilon, \\ P_-(z)J_Q(z)P_+^{-1}(z) & \text{for } z \in (-3i\epsilon, -i\epsilon) \cup (i\epsilon, 3i\epsilon). \end{cases} \quad (3.100)$$

3) As $z \rightarrow \infty$,

$$R(z) = I + \mathcal{O}(1/z).$$

In order to solve this RH problem asymptotically for large n , we need to show that the jump matrices for $R(z)$ are close to the identity matrix uniformly for $z \in \Sigma_R$, see Figure 5.

Lemma 3.25. *The jump matrix J_R in the RH problem for R satisfies for some constant $c > 0$,*

$$J_R(z) = \begin{cases} I + \mathcal{O}(\epsilon_n), & \text{for } |z| = 3\epsilon, \\ I + \mathcal{O}(1/n), & \text{for } |z \pm 1| = \delta, \\ I + \mathcal{O}(e^{-cn}), & \text{elsewhere on } \Sigma_R, \end{cases} \quad (3.101)$$

as $n \rightarrow \infty$, where the \mathcal{O} terms are uniform.

Proof. For $z \in \Sigma_R$ with $|z| > 3\epsilon$, we have $J_R(z) = J_Q(z)$. On the boundary of the disks around the endpoints we have $J_Q(z) = I + \mathcal{O}(n^{-1})$, see (3.51) and on the rest of Σ_R except $(-i\rho, i\rho)$ we have $J_Q(z) = I + \mathcal{O}(e^{-cn})$ for some $c > 0$, see (3.52).

On the circle $|z| = 3\epsilon$, the jump is $J_R(z) = P(z)^{-1}$. We use (3.56) and the fact that $\widehat{P}(z) = I + \mathcal{O}(\epsilon_n)$, uniformly for $|z| = 3\epsilon$, to find that

$$J_R(z) = P(z)^{-1} = I + \mathcal{O}(\epsilon_n),$$

as given in (3.101).

For $z \in (3i\epsilon, i\rho)$ we get from (3.100) and (3.53)

$$J_R(z) = J_Q(z) = D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 1 & 0 \\ j_1(z)(D_1(z)D_2(z))^2 & 1 \end{pmatrix} N_0^{-1}(z) D_\infty^{-\sigma_3}.$$

From (3.80) and (3.82), we obtain for $y \in [0, \rho]$,

$$|j_1(iy)(D_1(iy)D_2(iy))^2| \leq C_\nu y^\nu e^{-2ny}, \quad C_\nu > 0, \quad (3.102)$$

We also use (3.36) and then (3.101) for $z \in (3i\epsilon, i\rho)$ follows. The case $z \in (-i\rho, -3i\epsilon)$ can be handled in a similar way.

What is left are the intervals $(i\epsilon, 3i\epsilon)$ and $(-3i\epsilon, -i\epsilon)$. For $z \in (i\epsilon, 3i\epsilon)$ we find from (3.100) and (3.56) that

$$J_R(z) = D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \widehat{P}_-(z) \begin{pmatrix} 1 & -j_1(z)(D_1(z)D_2(z))^2 \\ 0 & 1 \end{pmatrix} \\ \times \widehat{P}_+^{-1}(z) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} N_0(z)^{-1} D_\infty^{-\sigma_3}.$$

Using (3.57)-(3.58) we rewrite this as

$$J_R(z) = I - j_1(z)(D_1(z)D_2(z))^2(1 - \chi(z))D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \widehat{P}_+(z) \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \\ \times \widehat{P}_+^{-1}(z) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} N_0(z)^{-1} D_\infty^{-\sigma_3}. \quad (3.103)$$

Here we note that $\det \widehat{P}(z) = 1$, which follows by standard arguments from the RH problem 3.15, and therefore $\widehat{P}_+^{-1} = \begin{pmatrix} \widehat{P}_{22} & -\widehat{P}_{12} \\ -\widehat{P}_{21} & \widehat{P}_{11} \end{pmatrix}_+$. Then a little calculation shows that (3.103) reduces to

$$J_R(z) = I + j_1(z)(D_1(z)D_2(z))^2(1 - \chi(z))\Lambda(z), \quad z \in (i\varepsilon, 3i\varepsilon), \quad (3.104)$$

where

$$\Lambda(z) = D_\infty^{\sigma_3} N_0(z) \begin{pmatrix} -\widehat{P}_{11}(z)\widehat{P}_{21}(z) & -\widehat{P}_{21}(z)^2 \\ \widehat{P}_{11}(z)^2 & \widehat{P}_{11}(z)\widehat{P}_{21}(z) \end{pmatrix} N_0^{-1}(z) D_\infty^{-\sigma_3}.$$

The functions \widehat{P}_{11} and \widehat{P}_{21} are analytic on $(i\varepsilon, 3i\varepsilon)$ and so we do not have to take the $+$ -boundary value.

Then it follows from (3.36) and the estimates in (3.95) and (3.97) that all entries in Λ are uniformly bounded as $n \rightarrow \infty$. Then by (3.80) and (3.104) we find (3.101) for $z \in (i\varepsilon, 3i\varepsilon)$. A similar argument shows that $J_R(z)$ is exponentially close to the identity matrix for $z \in (-3i\varepsilon, -i\varepsilon)$ as well, and the lemma follows. \square

As a consequence of (3.101), the biggest estimates for $J_R - I$ are on the circle $|z| = 3\varepsilon$. For $0 < \nu \leq 1/2$, the jump matrix satisfies (recall ϵ_n is given by (2.3))

$$J_R(z) = I + \mathcal{O}(\epsilon_n), \quad n \rightarrow \infty, \quad (3.105)$$

uniformly for $z \in \Sigma_R$ where Σ_R is the union of contours depicted in Figure 5. Note that $J_R(z) \rightarrow I$ as $n \rightarrow \infty$, but the rate of convergence is remarkably slow.

Following standard arguments, we now find that for n sufficiently large, the RH problem 3.24 for R is solvable, and

$$R(z) = I + \mathcal{O}(\epsilon_n), \quad n \rightarrow \infty, \quad (3.106)$$

uniformly for $z \in \mathbb{C} \setminus \Sigma_R$. The convergence rate in (3.106) may not be optimal, since some of the bounds in the analysis may not be as sharp as possible. Note that for $\nu = 1/2$ we only have $R(z) = I + \mathcal{O}(\frac{1}{\log n})$, which is a very slow convergence.

Since all of the transformations $X \mapsto U \mapsto T \mapsto S \mapsto Q \mapsto R$ are invertible, we then also find that the RH problem for X is solvable for n large enough. In particular we find that the polynomial $P_n = X_{11}$ exists for n large enough.

4 Proofs of the Theorems

4.1 Proof of Theorem 2.6

Proof. Following the transformations of the Deift–Zhou steepest descent analysis and using formula (3.106), we obtain asymptotic information about $\widetilde{P}_n(z) = U_{11}(z)$ in the complex plane, see (3.14) and (2.4). Consider the region in Figure 5 which is outside

the lens and outside of the disks around $z = \pm 1$. In this case $U_{11}(z) = T_{11}(z)e^{ng(z)}$, and by (3.21), (3.26), (3.50), (3.99),

$$T(z) = S(z) = Q(z)N(z) = R(z)N(z),$$

which means that

$$\begin{aligned} \tilde{P}_n(z)e^{-ng(z)} &= T_{11}(z) = R_{11}(z)N_{11}(z) + R_{12}(z)N_{21}(z) \\ &= N_{11}(z)(1 + \mathcal{O}(\epsilon_n)) + N_{21}(z)\mathcal{O}(\epsilon_n), \end{aligned} \quad (4.1)$$

using (3.106). Here ϵ_n is given again by (2.3). We observe that $N_{11} = D_\infty N_{0,11}(D_1 D_2)^{-1}$, from (3.45), and using (3.35), (3.36), (3.41) and (3.47) we get

$$N_{11}(z) = \left(\frac{z(z + (z^2 - 1)^{1/2})}{2(z^2 - 1)} \right)^{1/4} \left(\frac{(z^2 - 1)^{1/2} - i}{(z^2 - 1)^{1/2} + i} \right)^{-\nu/4} \left(1 + \mathcal{O}\left(\frac{\log n}{n}\right) \right), \quad (4.2)$$

as $n \rightarrow \infty$. Similarly, we also see that $N_{21}(z) = \mathcal{O}(1)$ as $n \rightarrow \infty$ and (2.9) follows.

Since the lens can be taken arbitrarily close to the interval $[-1, 1]$ and the disks can be taken arbitrarily small, the asymptotics (2.9) is valid uniformly on any compact subset of $\mathbb{C} \setminus [-1, 1]$. This proves Theorem 2.6. \square

4.2 Proof of Theorem 2.7

Proof. Inside the lens, but away from the endpoints and the origin, we use the relation (3.26) between the functions $T(z)$ and $S(z)$. Let z be in the lens with $\operatorname{Re} z > 0$. Then we have

$$T_{11}(z) = S_{11}(z) \pm S_{12}(z) \frac{e^{\frac{\nu\pi i}{2} - 2n\varphi(z)}}{W_n(z)},$$

for $\pm \operatorname{Im} z > 0$, and therefore

$$\tilde{P}_n(z) = e^{ng(z)} T_{11}(z) = e^{ng(z)} \left[S_{11}(z) \pm S_{12}(z) \frac{e^{\frac{\nu\pi i}{2} - 2n\varphi(z)}}{W_n(z)} \right].$$

Since $S(z) = Q(z)N(z)$ away from the endpoints, and $Q(z) = R(z)$ away from the origin (if $|z| > 3\epsilon$), see (3.50) and (3.99), we obtain

$$\tilde{P}_n(z) = e^{ng(z)} \left[N_{11}(z) \pm N_{12}(z) \frac{e^{\frac{\nu\pi i}{2} - 2n\varphi(z)}}{W_n(z)} + \mathcal{O}(\epsilon_n) \right]. \quad (4.3)$$

for $\operatorname{Re} z \geq 0$, and $\pm \operatorname{Im} z > 0$.

We are going to simplify the expression (4.3) and we do it for $\operatorname{Re} z > 0$, $\operatorname{Im} z > 0$. First we use (3.18), (3.19), and (3.17) in (4.3) to get

$$\tilde{P}_n(z) = \frac{e^{\frac{n\pi z}{2}}}{(2e)^n W_n(z)^{1/2}} \left[N_{11}(z) W_n(z)^{1/2} e^{n\varphi(z)} + \frac{N_{12}(z)}{W_n(z)^{1/2}} e^{\frac{\nu\pi i}{2} - n\varphi(z)} + \mathcal{O}(\epsilon_n) \right]. \quad (4.4)$$

From (3.45) we have $N_{11} = D_\infty N_{0,11}(D_1 D_2)^{-1}$, $N_{12} = D_\infty N_{0,12} D_1 D_2$ and so

$$\tilde{P}_n(z) = \frac{D_\infty e^{\frac{n\pi z}{2} + \frac{\nu\pi i}{4}}}{(2e)^n W_n(z)^{1/2}} \left[\frac{N_{0,11}(z) W_n(z)^{1/2}}{D_1(z) D_2(z)} e^{-\frac{\nu\pi i}{4} + n\varphi(z)} + \frac{N_{0,12}(z) D_1(z) D_2(z)}{W_n(z)^{1/2}} e^{\frac{\nu\pi i}{4} - n\varphi(z)} + \mathcal{O}(\epsilon_n) \right]. \quad (4.5)$$

Next we use (3.47) to write

$$N_{0,11}(z) = e^{-\frac{\pi i}{4}} \frac{f(z)^{1/2}}{\sqrt{2}(1-z^2)^{1/4}}, \quad N_{0,12}(z) = e^{\frac{\pi i}{4}} \frac{f(z)^{-1/2}}{\sqrt{2}(1-z^2)^{1/4}},$$

where $(1-z^2)^{1/4}$ denotes the branch that is real and positive for $-1 < z < 1$ and $f(z)$ is given by (3.48). Thus

$$\begin{aligned} \tilde{P}_n(z) &= \frac{D_\infty e^{\frac{n\pi z}{2} + \frac{\nu\pi i}{4}}}{\sqrt{2}(2e)^n (1-z^2)^{1/4} W_n(z)^{1/2}} \\ &\times \left[\left(\frac{f(z)^{1/2} W_n(z)^{1/2}}{D_1(z) D_2(z)} e^{n\varphi(z) - \frac{\nu\pi i}{4} - \frac{\pi i}{4}} + \frac{D_1(z) D_2(z)}{f(z)^{1/2} W_n(z)^{1/2}} e^{-n\varphi(z) + \frac{\nu\pi i}{4} + \frac{\pi i}{4}} \right) + \mathcal{O}(\epsilon_n) \right]. \end{aligned} \quad (4.6)$$

The two terms in parenthesis are inverse of each other. We write all contributing factors in exponential form. We have by (3.20), (3.15) and (3.42)

$$e^{n\varphi(z)} = \exp\left(\pi i n \int_z^1 \psi(s) ds\right) \quad (4.7)$$

$$D_2(z) e^{\frac{\nu\pi i}{4}} = \exp\left(-\frac{\nu\pi}{2} \psi(z)\right) \quad (4.8)$$

for $\operatorname{Re} z > 0$, $\operatorname{Im} z > 0$, and we note that by (3.25) and (3.35)

$$\frac{W_n(z)^{1/2}}{D_1(z)} = f(z)^{-1/4} \left(1 + \mathcal{O}\left(\frac{\log n}{n}\right) \right) \quad (4.9)$$

as $n \rightarrow \infty$. Finally, we write

$$f(z)^{1/2} = e^{\frac{i}{2} \arccos z}, \quad \operatorname{Im} z > 0 \quad (4.10)$$

and inserting (4.7)–(4.10) into (4.6) we find (2.12), where we also use (3.25), (3.36) to simplify the first factor.

A similar calculation leads to the same formula (2.12) for $z \in E$ with $\operatorname{Re} z > 0$ and $\operatorname{Im} z < 0$. \square

4.3 Proof of Theorem 2.1

Proof. It follows from (4.1) and (4.2) that the leading factor in the outer asymptotics of $P_n(in\pi z)$ does not vanish for $z \in \mathbb{C} \setminus [-1, 1]$.

Let $\tilde{P}_n(z) = (in\pi)^{-n} P_n(in\pi z)$ be the monic polynomial. Then we find from (2.8) that

$$\lim_{n \rightarrow \infty} \frac{1}{n} \log |\tilde{P}_n(z)| = \operatorname{Re} g(z) = \int_{-1}^1 \log |z - x| \psi(x) dx, \quad (4.11)$$

uniformly for z in compact subsets of $\mathbb{C} \setminus [-1, 1]$. This implies that for any given compact subset $K \subset \mathbb{C} \setminus [-1, 1]$, the polynomial \tilde{P}_n does not have any zeros in K for n large enough. In other words, all zeros of \tilde{P}_n tend to the interval $[-1, 1]$ as $n \rightarrow \infty$.

In addition we find from (4.11) that the zeros of \tilde{P}_n have $\psi(x)$ as limiting density. This follows from standard arguments in potential theory, see e.g. [19]. This proves Theorem 2.1. \square

4.4 Proof of Theorem 2.2

Let E be the neighborhood of $(-1, 1)$ as in Theorem 2.7. Theorem 2.2 will follow from the asymptotic approximation (4.3) that is valid uniformly for z in

$$E_\delta = E \setminus (D(-1, \delta) \cup D(0, \delta) \cup D(1, \delta))$$

with $\operatorname{Re} z \geq 0$.

Lemma 4.1. *There is a constant $C > 0$ such that for large n all zeros in E_δ satisfy*

$$\left| \operatorname{Re} \frac{\nu\pi}{2} \psi(z) - \operatorname{Im} \theta_n(z) \right| < C\epsilon_n. \quad (4.12)$$

Proof. It is enough to consider $\operatorname{Re} z \geq 0$.

Let

$$F_n(z) = \exp \left(\frac{\nu\pi}{2} \psi(z) + i\theta_n(z) \right)$$

Then by (2.12) we have that zeros of \tilde{P}_n in E_δ with $\operatorname{Re} z > 0$ are in the region where

$$F_n(z) \left(1 + \mathcal{O} \left(\frac{\log n}{n} \right) \right) + F_n(z)^{-1} \left(1 + \mathcal{O} \left(\frac{\log n}{n} \right) \right) = \mathcal{O}(\epsilon_n).$$

This leads to

$$F_n(z) + F_n(z)^{-1} = \mathcal{O}(\epsilon_n),$$

and so there is a constant $C > 0$ such that all zeros in E_δ satisfy

$$|F_n(z) + F_n(z)^{-1}| \leq C\epsilon_n \quad (4.13)$$

if n is large enough.

Note that

$$|F_n(z)| = \exp \left(\operatorname{Re} \frac{\nu\pi}{2} \psi(z) - \operatorname{Im} \theta_n(z) \right).$$

Thus if (4.12) is not satisfied then either $|F_n(z)| \geq \exp(C\epsilon_n)$ or $|F_n(z)| \leq \exp(-C\epsilon_n)$. In both cases it follows that

$$|F_n(z) + F_n(z)^{-1}| \geq e^{C\epsilon_n} - e^{-C\epsilon_n} \geq 2C\epsilon_n.$$

Because of (4.13) this cannot happen for zeros of \tilde{P}_n in E_δ if n is large enough, and the lemma follows. \square

The lemma is the main ingredient to prove Theorem 2.2.

Proof of Theorem 2.2. In the proof we use c_1, c_2, \dots , to denote positive constants that do not depend on n or z . The constants will depend on $\delta > 0$.

It is easy to see from the definition (2.11) that $\theta'_n(x) \leq c_1 n < 0$ for $x \in (0, 1 - \delta)$. This implies that for some constant $c_2 > 0$

$$\operatorname{Im} \theta_n(z) \begin{cases} \leq -c_2 n \operatorname{Im} z & \text{for } z \in E_\delta, \operatorname{Re} z > 0, \operatorname{Im} z \geq 0 \\ \geq c_2 n |\operatorname{Im} z| & \text{for } z \in E_\delta, \operatorname{Re} z > 0, \operatorname{Im} z < 0 \end{cases} \quad (4.14)$$

There are also constants $c_3, c_4 > 0$ such that

$$c_3 < \operatorname{Re} \frac{\nu\pi}{2} \psi(z) < c_4, \quad z \in E_\delta, \operatorname{Re} z > 0, \quad (4.15)$$

see (2.10). Thus if $\operatorname{Im} z \geq 0$ then by (4.14) and (4.15)

$$\left| \operatorname{Re} \frac{\nu\pi}{2} \psi(z) - \operatorname{Im} \theta_n(z) \right| \geq c_2 n \operatorname{Im} z + c_3 \geq c_3 > 0$$

and thus there are no zeros in E_δ with $\operatorname{Im} z \geq 0$ by Lemma 4.1 if n is large enough.

For $\operatorname{Im} z \leq 0$ we have by (4.14) and (4.15)

$$\left| \operatorname{Re} \frac{\nu\pi}{2} \psi(z) - \operatorname{Im} \theta_n(z) \right| \geq c_2 n |\operatorname{Im} z| - c_4$$

It follows from this and Lemma 4.1 that for large n , there are no zeros with $\operatorname{Im} z \leq -\frac{c_5}{n}$ if $c_5 > c_4/c_2$.

Now assume $z \in E_\delta$ with $-\frac{c_5}{n} < \operatorname{Im} z < 0$ and $\operatorname{Re} z > 0$. Write $z = x + iy$. Then by Taylor expansion

$$\frac{\nu\pi}{2} \psi(z) = \frac{\nu\pi}{2} \psi(x) + \mathcal{O}(1/n)$$

and, see also (2.11),

$$\begin{aligned} \theta_n(z) &= \theta_n(x) + iy\theta'_n(x) + \mathcal{O}(1/n) \\ &= \theta_n(x) - iyn\pi\psi(x) + \mathcal{O}(1/n) \end{aligned}$$

and \mathcal{O} terms are uniform for z in the considered region.

Then since $\psi(x)$ and $\theta_n(x)$ are real, we have

$$\begin{aligned} \operatorname{Re} \frac{\nu\pi}{2}\psi(z) - \operatorname{Im} \theta_n(z) &= \frac{\nu\pi}{2}\psi(x) + yn\pi\psi(x) + \mathcal{O}(1/n) \\ &= \left(\frac{\nu}{2} + ny\right) \pi\psi(x) + \mathcal{O}(1/n) \end{aligned}$$

Thus if $|\frac{\nu}{2} + ny| \geq c_6\epsilon_n$ then by the above and (4.15)

$$\left| \operatorname{Re} \frac{\nu\pi}{2}\psi(z) - \operatorname{Im} \theta_n(z) \right| \geq \frac{2c_6c_3}{\nu}\epsilon_n + \mathcal{O}(1/n)$$

and from Lemma 4.1 it follows that $z = x + iy$ is not a zero if c_6 is large enough.

Thus for large n all zeros $z = x + iy$ of \tilde{P}_n in E_δ satisfy

$$\left| \frac{\nu}{2} + ny \right| \leq c_6\epsilon_n.$$

Then $in\pi z$ is a zero of P_n , see (2.4), and the real part of this zero is $-n\pi y$ which differs from $\frac{\nu\pi}{2}$ by an amount less than $\pi c_6\epsilon_n$. This proves Theorem 2.2. \square
