Running head: Oxidative stress in *Buccinanops globulosus*

[*]Corresponding author: S. E. Sabatini, e-mail: *sabatini@bg.fcen.uba.ar*

ABSTRACT

The gastropod Buccinanops globulosus *is commonly used as bioindicator of tributyltin (TBT) contamination due to its high imposex incidence in maritime traffic areas. The aim of this study was to evaluate both oxidative stress in* B. globulosus *at three sites with different maritime activity, and imposex incidence in Nuevo gulf, Argentina. Oxidative stress parameters in digestive glands, like superoxide dismutase (SOD) and glutathione-S-transferase (GST) activities, reduced glutathione levels (GSH), and oxidative damage to lipids, estimated as thiobarbituric acid reactive substances (TBARs) as well as imposex parameters (% imposex and female penis length -FPL-) were measured in females. Gastropods from the harbour area showed 100% imposex, the highest FPL and TBARs content, as well as GSH levels and SOD activity.*

The different oxidative stress responses and high imposex incidence at the harbour site may indicate a negative effect on the organism's physiological state due to environmental pollution.

Keywords: Oxidative stress, imposex, marine pollution, *Buccinanops globulosus,* Nassariidae.

INTRODUCTION

Pollutants such as tributyltin (TBT), polyaromatic hydrocarbons (PAHs), organochlorinated compounds and trace metals are present in areas with intense maritime activity in Patagonian coasts (Gil *et al.*, 1999; Commendatore *et al.*, 2000; Esteves *et al.*, 2006; Gil *et al.*, 2006; Commendatore & Esteves, 2007; Massara Paletto *et al.*, 2008; Bigatti *et al.*, 2009). Aquatic invertebrates, and mollusks in particular, are widely been used as bioindicators of polluted environments (Meador *et al.*, 1995; Kim *et al.*, 2002; Antizar-Ladislao, 2008), while biomarkers are powerful tools to detect environmental damage and risk status (Dahlhoff, 2004). Pollutants could affect living organisms by inducing reactive oxygen species (ROS) formation (Winston & Di Giulio, 1991; Cheung *et al.*, 2001; Leonard *et al.*, 2004; Nicholson & Lam, 2005). Oxidative stress is the result of the imbalance between the generation and neutralization of ROS by antioxidant mechanisms (Davies, 1995). Oxidative stress responses (e.g. antioxidant enzymes activities and/or oxidative damage to lipids) have been used as biomarkers in mollusks to test and quantify the toxic effects of pollutants in the aquatic environment (de Almeida *et al.*, 2004; Belcheva *et al.*, 2011; Sabatini *et al.*, 2011a). The increased activity or *de novo* synthesis of antioxidant enzymes to mitigate oxidative damage has been considered as an adaptation of organisms to stress conditions (Young & Woodside, 2001). Among these enzymes are superoxide dismutase (SOD), glutathione peroxidase (GPx) and catalase (CAT) which protect ROS scavenging cells (Karacoc *et al.*, 1997; Borković *et al.*, 2005) and glutathione S-transferase (GST) as well, a phase II detoxifying enzyme, exhibiting a protective mechanism against oxidative stress (Prohaska**,** 1980; Sheehan and Power, 1999; Doyen *et al.,* 2005). Moreover, aquatic organisms also present non enzymatic antioxidant defenses (e.g. vitamin E, reduced glutathione-GSH-, between others) contributing to minimize oxidative damage (Sayeed *et al.,* 2003; Wang *et al.,* 2008).

In mollusks, the digestive gland is the principal site for bioaccumulation and detoxification of pollutants and the main target of oxidative disruption (Malanga *et al.*, 2004). In several bivalves species exposed to pollutants, oxidative damage and the increase/decrease of the activity of antioxidant enzymes have been registered (Bainy *et al.*, 2000; Sabatini *et al.*, 2009, 2011a,b; Giarratano *et al.*, 2010; Di Salvatore *et al.*, 2013; Giarratano *et al.*, 2013).

In marine gastropods from the Argentinean coast, the imposex phenomenon (penis or *vas deferens* neoformation) in females exposed to tributyltin (TBT) (Gibbs & Bryan,

1986) has been detected in all the harbour areas (Bigatti *et al.*, 2009). Many gastropod species have been affected by imposex in Argentina, while the nassarid *Buccinanops globulosus* showed high sensibility to TBT (Bigatti *et al.*, 2009). It has been demonstrated that TBT could induce imposex, shell malformation (Chagot *et al.*, 1990; Alzieu, 2000; Bigatti & Carranza, 2007; Márquez *et al.*, 2011), and also causes oxidative stress (Huang *et al.,* 2005; Wang *et al.,* 2005; Jia *et al.,* 2009; Zhou *et al.,* 2010).

The gastropod *Buccinanops globulosus* inhabits sandy or muddy bottoms of shallow waters (Pastorino, 1993) in Patagonian coasts, and most of the time lives buried in the sediment (Scarabino, 1977). It is distributed along South Western Atlantic Ocean (Pastorino, 1993). *B. globulosus* is dioecious, with internal fertilization. Females attached the egg capsules to their own shells (Penchaszadeh, 1971), and are larger than the males. In general, the populations from Patagonia have shown variability in biological parameters such as growth, shell shape and aging (Narvarte *et al.,* 2008; Avaca *et al.,* 2013; Bökenhans *et al.,* 2014; Primost *et al., in press*). This species is edible and is part of an expanding artisanal fishery (Narvarte *et al.,* 2008, Averbuj *et al.,* 2014). Sublethal effects and bioaccumulation of TBT and other pollutants (trace metals, hydrocarbons) have been detected in harbour areas (Bigatti *et al.,* 2009; Torres *et al.,* 2013; Primost, 2014). While signalling by retinoid X receptors (RXR) (Nishikawa *et al.,* 2004) could be involved on the imposex development in gastropods although the induction mechanisms are under study, the determination of oxidative stress responses in gastropods imposex-affected still remains inconclusive in Argentina.

The aim of this study was to evaluate oxidative stress responses associated to maritime traffic contamination in imposex affected *B. globulosus* from Nuevo gulf, Patagonia Argentina.

MATERIALS AND METHODS

Study area and imposex incidence

The study was performed in three sites of Nuevo gulf, with decreasing maritime activity: harbour area at Luis Piedra Buena harbour (LPB) (42 º 43 ' 57 " S, 65 ° 1 ' 53.9 " W), Punta Cuevas beach (PC) (42 º 46 ' 45 " S, 64 º 59 ' 34 " W) and Cerro Avanzado beach (CA) (42 º 49 ' 37.66 " S, 64 º51 ' 29.19 " W) (Figure 1). In the LPB site activity of large vessels is frequently present (~720 vessels per year) (APPM, 2013); in this area 100% imposex was reported in gastropods since year 2000 (Bigatti & Penchaszadeh,

2005; Bigatti *et al.*, 2009; del Brío, 2011; Primost, 2014), while moderate pollution by PAHS, trace metals and TBT were previously recorded in sediments and mollusks (Gil *et al.*, 1999; Massara Paletto *et al.*, 2008; Bigatti *et al.*, 2009). PC site is a recreational public area frequently presenting diving vessels, where low pollution by TBT and trace metals were measured (Primost, 2014) and lesser imposex parameters were reported (Bigatti *et al.*, 2009; Primost, 2014). CA beach is a recreational area where very low or null imposex incidence was reported as well as not detectable TBT pollution (Bigatti *et al.*, 2009; del Brío, 2011; Primost, 2014); in this area low maritime traffic and sport vessels are present only occasionally. Table 1 summarized the pollution levels previously detected in the sampling sites.

Adult female gastropods *Buccinanops globulosus* (25 approximately at each site) were collected using baited traps. The sex was determinate *in situ* by presence or absence of the ventral pedal gland (only present in females) used to fix egg-capsules on its own shell. Total shell length (TSL) and body weight relative to size (BW) was recorder in the laboratory. Incidence of imposex (% I) was considered as the percentage of females with a penis or *vas deferens* development; correspondingly mean female penis length (FPL) was estimated only in females with penis development and using 0.1 mm precision digital caliper.

Oxidative stress parameters

In a subsample of 9 females per site, oxidative stress parameters were determinate. Digestive gland was carefully dissected, weighed (with a digital scale 0.01 g) and frozen at -80°C for later oxidative stress determinations.

Digestive glands were homogenized with 0.154 M KCl (1:5 w/v) containing 0.5 mM phenylmethylsulfonyl fluoride (PMSF) and 0.2 mM benzamidine (protease inhibitors) to study oxidative stress parameters. The homogenates were centrifuged at 12,000 x g during 30 minutes (4 ºC) and the supernatants were stored for later determinations.

Total soluble protein content was measured by the method of Bradford, (1976), using bovine serum albumin as standard. The results were expressed as µg of total protein per mL.

Superoxide dismutase (SOD, EC 1.15.1.1) activity was assessed by inhibition of photoreduction of NBT (nitroblue tetrazolium) and monitoring absorbance at 560 nm according to Beauchamp & Fridovich, (1971). The standard assay mixture contained 5, 10 and 15 µL enzymatic sample, 0.1 mM EDTA, 13 mM DL-methionine, 75 µM NBT

and 20 µM riboflavin, in 50 mM phosphate buffer (pH 7.5), to a final volume of 3 ml. Samples were exposed for 15 min to intense cool-white light, and then kept in the dark until absorbance was measured at 560 nm. Results were expressed as U per mg protein. A SOD unit was defined as the enzyme amount necessary to inhibit 50% the reaction rate.

Glutation-S-tranferase (GST, EC1.11.1.9) activity was measured by monitoring the absorbance at 340 nm using a 1-chloro-2,4dinitrobencene (CDNB) (100 mM) as substrate according to Habig *et al.*, (1974). Briefly we mixed 10 µL of GSH (100 mM in phosphate buffer) and 20 µL of sample in 960 µL of 100 mM phosphate buffer (pH 6.5) and 10 µL CDNB. One GST Unit was defined as the amount of enzyme needed to catalyze the formation of 1 µmol of GS-DNB per minute at 25 ºC.

Reduced glutathione (GSH) levels were determinate monitoring the absorbance at 412 nm after 30 min incubation at room temperature following the Anderson procedure (1985). Briefly, 100 µL supernatant from the 11,000 × g sample was acidified with 50 µL of 10% sulfosalicylic acid. After centrifugation at 8000 × for 10 min, supernatant (acid-soluble GSH) aliquots were mixed with 6 mM 5,5-dithiobis-(2-nitrobenzoic) acid (DTNB) in 0.143 M buffer sodium sulfate (pH 7.5), (containing 6.3 mM EDTA). Results were expressed as nmol GSH per mg of protein.

Lipid peroxidation was determined measuring thiobarbituric acid reactive substances (TBARs) according to Vavilin *et al.*, (1998). Briefly, the 11,000 x g supernatant (175 µL) from total homogenate was mixed with thiobarbituric acid (TBA) (26 mM) solution and incubated at 95-100 ºC for 45 min. After cooling, the reaction mixture was centrifuged and the supernatant absorbance was determined at 535 nm. TBARs concentration was estimated using an extinction coefficient of 156 $mM^{-1}cm^{-1}$ and absorbance determination at 535 nm. Results were expressed as µmol TBARs per mg of protein.

Statistical analysis

Normality and homogeneity of variances were tested by Lilliefors' and Bartlett's tests, respectively (Sokal & Rohlf, 1979). Results from size, weight and oxidative stress parameters were analyzed by one way ANOVA followed by a Tukey´s post hoc test. Results for imposex analysis were compared between sites by Kruskal Wallis followed by a Dunn post hoc test. Differences were considered significant with $P<0.05$. Statistica7 software was used for statistical analysis. A DistLM multiple correlations

was performed using PRIMER software (Clarke & Gorley, 2006**)** to compare the effect of stress parameters (as co-variable) on penis length (as response variable). Prior to analyze, variables were transformed by Z-score using R software (https://www.r-project.org/).

RESULTS

Imposex incidence

A total of 66 females of *Buccinanops globulosus* were analyzed for imposex incidence and a subsample of 27 females (9 per site) were used for the determination of oxidative stress parameters. Total shell length (TSL) and body weight (BW) were significantly different between sites (TSL: $F=27.306$, $p<0.0001$, $df=2$, $N=66$; BW: $F=46.006$, $p<0.0001$, $df=2$, $N=66$). In both cases, the highest values were obtained in LPB site (Table 2).

The imposex incidence was 100% in LPB (Table 2) and significant differences in female penis length (FPL) between LPB vs. PC sites were observed ($U=450.000$, $p<0.0001$, $N=43$). In CA site, the FPL was not calculated because only one female showed imposex development (with a small incipient penis).

Antioxidant defenses

In order to analyse the antioxidant defenses, results firstly showed that total protein content in the digestive gland did not differ between sampling sites ($F=0.220$, $p=0.804$, $df=2$, $N=27$) (data not shown). Therefore, all measured variables were standardized as a function of protein content.

Gastropods collected from the harbour area (LPB site) showed higher superoxide dismutase (SOD) activity than those from the others two sites (PC and CA) ($F=13.277$, $p=0.0001$, $df=2$, $N=27$) (Figure 2A). Also the reduced glutathione content (GSH) revealed a similar pattern, showing the highest values in LPB site ($F=8.148$, $p=0.002$, $df=2$, $N=27$), (Figure 2C).

On the other hand, Glutathione-s-tansferase (GST) activity in digestive gland did not show significant differences between sampling sites ($F=2.342$, $p=0,118$, $df=2$, $N=27$) (Figure 2B).

Oxidative damage

In relation to oxidative damage, significant differences in lipid peroxidation among sites

were obtained (TBARs: F=6.357, p=0.006, df=2, N=27), individuals collected in LPB site showed the highest values (Figure 3).

Stress parameters and imposex response

Significant differences were obtained in DistLM for SOD, GSH and TBAR variables on penis length (as response variable). These results showed that 61.5% of variability in penis length was explained by stress parameters (Table 3).

DISCUSSION

The imposex incidence and female penis length (FPL) recorded in this work for *Buccinanops globulosus* could be related to maritime traffic and levels of TBT reported previously in Nuevo gulf (Bigatti *et al.*, 2009; del Brío, 2011). Pollutants could be bioaccumulated in aquatic organisms affecting their defense mechanisms (Regoli & Principato, 1995; Chandran *et al.*, 2005; Chen *et al.*, 2011). In LPB area, del Brío *and coll.* detected butyltin levels (TBT + dibutyltin-DBT- + monobutyltin-MBT-) up to 265.8 ng (Sn) g^{-1} dry weight (dw) in sediments and up to 567.8 ng (Sn) g^{-1} (dw) in the tissues of the marine gastropod *Odontocymbiola magellanica*, being gonads and digestive gland the organs with the highest TBTs concentration (del Brio *et al.*, 2011). Also polyaromatic hydrocarbons such anthracene, benzo(b)fluoranthene (Torres *et al.*, 2013) and trace metals as copper (Cu), iron (Fe), lead (Pb) and zinc (Zn) were detected in *B. globulosus* (Primost, 2014) in LPB area confirming the capacity of these gastropod species to bioaccumulate different pollutants and potentially formation of reactive oxygen species (ROS).

ROS formation and changes in the oxidative balance have been observed as a result of exposure to environmental levels of TBT in bivalves (Huang *et al.*, 2005; An *et al.*, 2009) and gastropods (Jia *et al.*, 2009; Gopalakrishnan *et al.*, 2011). Imposex in *B. globulosus* was associated with TBT presence (Bigatti *et al.*, 2009) in the LPB area. In this work, the oxidative stress responses registered in imposexed gastropods could be attributed to TBT and other contaminants detected at LPB harbour area such as trace metals and PAHs (Gil *et al.*, 1988; Gil *et al.*, 1999; Commendatore *et al.*, 2000; Gil *et al.*, 2006; Di Salvatore *et al.*, 2013; Torres *et al.*, 2013; Primost, 2014).

It is well known that a wide range of pollutants enhance enzymatic and non-enzymatic antioxidants in marine invertebrates to protect cells against oxidative damage (Livingstone, 2001; Brown *et al.*, 2004; Valavanidis *et al.*, 2006). Our results show

highest SOD activities and highest concentrations of reduced glutathione in the digestive gland of gastropods from the LPB site. However, the glutathione-s-transferase (GST) activity showed a different pattern compared with these former antioxidant responses, where no significant differences in its activity were observed among the three sampling sites. Glutathione-S-transferase (GST) is a biotransformation enzyme which catalyzes the conjugation of electrophilic pollutants with reduced glutathione (GSH). The resulting conjugates increase their water solubility favoring the excretion processes (Armstrong, 1997; Hayes *et al.*, 2005). In mollusks, the activity of GST usually increases in relation to detoxification process (Almeida *et al.*, 2005; Huang *et al.*, 2005). However in 2005, Huang *and coll.* determinate that GST activity in the fish *Meretrix meretrix* may be increased or inhibited depending on the high or low TBT concentration in water, respectively (Huang *et al.,* 2005). Our results shows that pollution present in PC site would induce a low increase of GST activity in the digestive gland of *B. globulosus*, while the pollutant presence in CA environment were not enough to produce changes in GST activity. In the present work, antioxidants (SOD and GSH) increased in the proximity of the harbour area, which was in concordance with higher imposex levels and penis length. Former studies, in the same sampling area, related to oxidative stress responses in the bivalve *Aulacomya atra* have detected seasonal changes in the antioxidant defenses in relation to trace metal exposure and environmental pollution (Di Salvatore *et al.*, 2013; Giarratano *et al.*, 2013). In both studies, animals from the harbour area were the most affected, showing an increase in the antioxidant defenses and also suffering higher oxidative damage to lipids. Meanwhile, a study in the fish *Sebastiscus marmoratus* exposed to TBT also revealed an increase in SOD activity in the liver (Wang *et al.*, 2005). In this sense, SOD increasing in *B. globulosus* probably could be related to TBT contamination detected recently in the area (Bigatti *et al.*, 2009; del Brío *et al.*, 2011).

Lipid peroxidation has been also reported as a principal cause of cellular damage induced by oxidative stress conditions (Valavanidis *et al.*, 2006). Membrane alterations in mollusks are the major target of cellular damage in organisms exposed to trace metals and other toxic substances (Viarengo *et al.*, 1990; Viarengo *et al.*, 1991). In the present work, *B. globulosus* showed a marked increment in lipid peroxidation in the digestive gland of gastropods collected from the harbour area compared to animals from CA and PC sites. In addition, our results are in accordance to those reported by Zhou *et al.* (2010), where TBT exposures increase lipid peroxidation (measured as

malondialdehyde (MDA) levels) in the abalone *Haliotis diversicolor supertexta*. Similar results were also observed in laboratory studies where rats exposed to repeated TBT doses increment the MDA levels (Liu *et al.*, 2006); Bernat *and coll.* also reported the same effect in the filamentous fungus *Cunninghamella elegans* exposed to TBT (Bernat *et al.*, 2014).

Our results suggest that the differences in terms of oxidative stress responses and high imposex incidence observed in *B. globulosus* at the harbour site indicate a negative effect on its physiological state of the species due to pollutants presence in the aquatic environment. The possible relationship between induction mechanism of imposex and oxidative stress should be tested in controlled experiments exposing normal and imposexed individuals to TBT, followed by comparative measurement of oxidative stress parameters in comparing experimental groups.

CONCLUSIONS

In conclusion, both oxidative stress responses and imposex incidence were increased in gastropods inhabiting the harbour area. While *B. globulosus* suffers an increase of the antioxidant defenses (SOD activity and GSH content), an oxidative damage to lipids (TBARs levels) was still observed.

This is the first study on oxidative stress responses associated to marine pollution in an edible gastropod affected by imposex in Argentina. Although TBT is not the only pollutant present in the harbour area, further integrated studies are necessary to evaluate the role of oxidative stress responses in *Buccinanops globulosus* as biomarkers of TBT presence.
