SUMMARY
In previous works, we presented 2-D and 3-D magnetotelluric modelling methods based on Rayleigh–Fourier expansions. These methods are an alternative to finite-element and finite-difference techniques and are especially suitable for modelling multilayered structures, with smooth irregular boundaries. Here we generalize the 2-D method for the calculation of the electromagnetic response of 2-D structures to arbitrary, spatially non-uniform 2-D and 3-D inducing magnetic fields. These fields are characteristic of low- and high-latitude regions. We calculate the response to different 2-D and 3-D sources, of a 2-D structure representative of the conductivity distribution which could be found at a coastline, which includes deep conductive anomalies in the lower crust and upper mantle. Then, we investigate source effects, comparing these responses to that obtained for a uniform source.

These effects become noticeable for periods greater than approximately 6 h and increase with the period of the source. They are highly dependent on the morphology of the source and also on the orientation of the external field relative to the strike direction of the structure. In various cases, they totally mask the uniform source response.

Key words: daily variations, geo-electromagnetic induction, non-uniform inducing fields, source effects.

1 INTRODUCTION
The basic hypothesis of spatially uniform (1-D) inducing magnetic fields, used for magnetotelluric (MT) modelling of the earth resistivity distribution (Tikhonov 1950; Cagniard 1953), has proved to work well in many cases, and its validity implies that the MT transfer functions depend only on the electrical structure of the earth, and not on the unknown external field. This assumption is also frequently employed to interpret data from geomagnetic deep soundings (GDS) (Schultz & Larsen 1987; Bahr & Filioux 1989). Its validity simplifies fieldwork because it implies that data do not need to be collected simultaneously at the different sounding locations. Dimitriev & Berdichevsky (1979) demonstrated that the single-site approach is also valid for sources varying linearly over length-scales exceeding the skin depth. Nevertheless, in certain cases, e.g. for studies performed at low or high latitudes, and especially for hourly or greater periods, these hypotheses usually fail due to the presence of the equatorial or auroral electrojets. When this happens, the models obtained assuming 1-D sources for the deep conductivity distribution (particularly for the lower crust and the upper and mid mantle) contain source distortions (Srivastava 1965; Quon et al. 1979; Mareschal 1981; Osipova et al. 1989; Pirjola 1992; Vilhanen 1996; Padilha et al. 1997; Vilhanen et al. 1999).

When data are simultaneously acquired at all sounding sites it is not necessary to assume 1-D inducing fields. Some decades ago, various large 1-D or bi-dimensional (2-D) arrays of magnetometers were deployed around the world to study both the electrical structure of the crust and upper mantle and the morphology of the external magnetic field. One example is the EMSLAB array (Gough et al. 1989). In recent years advances in instrumentation made more feasible the simultaneous acquisition of data in 2-D arrays of fully digital MT stations, as has been done in the BEAR project in Europe (Korja 1998). Then, the development of methods to calculate the earth response to non-spatially uniform sources becomes necessary, to take full advantage of these facilities. Hakkinen & Pirjola (1986) solved the problem of tri-dimensional (3-D) inducing fields over 1-D layered earths exactly. Then, Pirjola (1992) and Vilhanen et al. (1993) investigated magnetotelluric source effects

produced by inductive fields using simplified models of an auroral electrojet over a 1-D layered earth and a 2-D, two-layer (the deeper being a perfect conductor) model. Later, Boteler & Pirjola (1998) and Pirjola & Vilhanen (1998) calculated the response of 1-D layered earths to 3-D sources representing auroral electrojets using the complex image method (CIM), previously suggested by Wait & Spies (1969). Then applying the CIM, which simplifies and accelerates the calculations, Vilhanen et al. (1999) made a more complete study of magnetotelluric source effects over 1-D earths due to different kinds of sources associated with auroral electrojets. On the other hand, Carrasquilla & Rijo (1998) studied how source effects produced by 2-D sources representing the equatorial electrojet modify the response of 3-D conductive bodies. To do so they generalized the 3-D integral equations (IE) magnetotelluric modelling method by Wannamaker et al. (1984).

In a previous work, Osella & Martinelli (1993) presented a bi-dimensional MT modelling method, based on the application of Rayleigh–Fourier (RF) techniques. This method is an alternative to finite-difference (FD) (Smith & Booker 1991) and finite-element (FE) (Wannamaker et al. 1987) solutions. It is especially suited to modelling multilayered structures, with smooth irregular contours. Later, Osella et al. (1993a) generalized this method to include non-uniform, 2-D, transverse electric (TE) sources with the same strike as the 2-D structures. Using this method, Osella et al. (1993a,b) and Favetto et al. (1997) modelled the daily variations of the geomagnetic fields at Peru and Argentina, considering the morphology of the sources (in the first case, the equatorial electrojet), obtaining information concerning the regional conductivity distribution in these zones up to depths of the order of 600–800 km. Martinelli & Osella (1997) also developed a MT, 3-D, RF modelling method.

In the present paper, we extend our previous RF methods to the calculation of the electromagnetic response of this type of 2-D structure to arbitrary 2-D or 3-D inducing fields. In order to make the method even more general, and applicable to a wider range of periods than those involved in MT or induction arrays modelling (for example, such as used in controlled source soundings), we do not impose the validity of the quasi-stationary approximation in the derivations.

Then, applying this development, we perform a theoretical study of the long-period source distortions that could appear at coastlines, as a function of the morphology of the inducing fields.

## 2 Electromagnetic response of 2-D multilayered structures to 3-D inducing fields

In the following, we obtain the response of a 2-D, N-layered model, with smooth, irregular boundaries, to 3-D inducing fields. Fig. 1 shows the proposed earth model. Each medium \( n \), for \( 1 \leq n \leq N \), has conductivity \( \sigma_n \), dielectric permittivity \( \varepsilon_n \), and magnetic permeability \( \mu_0 \) equal to that of free space. Boundaries between layers are given by functions \( z = S_n(x) \). The external magnetic field, \( \vec{H}_{\text{ext}} \), has a time dependence \( \exp(i\omega t) \) and is a function of the coordinates \( x, y \) and \( z \); its \( x \) and \( y \) components at the earth surface are known. Then, inside each layer \( n \), the electric, \( \vec{E}_n \) and magnetic, \( \vec{H}_n \), fields satisfy (Weaver 1994)

\[
\nabla \times \vec{E}_n = -i\omega \mu_0 \vec{H}_n \tag{1}
\]

\[
\nabla \times \vec{H}_n = (\sigma_n + i\omega \varepsilon_n) \vec{E}_n. \tag{2}
\]

In the air (medium 0), far from the sources:

\[
\nabla \times \vec{E}_0 = -i\omega \mu_0 \vec{H}_0 \tag{3}
\]

\[
\nabla \times \vec{H}_0 = i\omega \mu_0 \vec{E}_0, \tag{4}
\]

where \( \varepsilon_0 \) is the dielectric permittivity of vacuum.

The studied area has lengths \( L_x \) and \( L_y \) along the \( x \) and \( y \) directions, respectively. We choose an extension of the model outside this area that simplifies the treatment. In this extended model the interfaces \( S_n \) are even and periodic functions of \( x \), and the external magnetic

![Figure 1. Generic 2-D electrical model.](image)
field, \(\vec{H}^{(\text{ext})}\), is a periodic function of \(x\) and \(y\). This external field is the sum of two contributions, \(\vec{H}^{(\text{inc})}\) and \(\vec{H}^{(\text{pol})}\), where the \(x\) component of \(\vec{H}^{(\text{inc})}\), \(H^{(\text{inc})}_{x}\), and the \(y\) component of \(\vec{H}^{(\text{pol})}\), \(H^{(\text{pol})}_{y}\), are even functions of \(x\) and \(y\), and the \(y\) component of \(\vec{H}^{(\text{inc})}\), \(H^{(\text{inc})}_{y}\), and the \(x\) component of \(\vec{H}^{(\text{pol})}\), \(H^{(\text{pol})}_{x}\), are odd functions of \(x\) and \(y\). The spatial periodicities are named \(\lambda_{x}\) and \(\lambda_{y}\). The studied area is centred at \((x, y) = (\lambda_{x}/4, \lambda_{y}/4)\). Later, we explain in detail how we construct the extended model that satisfies these conditions. At the present, we only mention that the selected extension implies no loss of generality on the type of interfaces and external fields that can be modelled, and does not affect the results obtained in the target region, provided that \(\lambda_{x}\) and \(\lambda_{y}\) are much greater than \(L_{x}\) and \(L_{y}\), respectively. We assume that Rayleigh scattering theory is valid on every boundary, so, the general solutions for the magnetic and electric field components, which are also periodic with \(x\) and \(y\), can be written as the following expansions:

\[
H^{(\text{inc})}_{x}(x, y, z, \omega) = \sum_{n, m \in \mathbb{Z}} \left[ A^{(\text{inc})}_{nm}(\omega) \exp \left[ R^{(\text{inc})}_{nm}(\omega)z \right] + B^{(\text{inc})}_{nm}(\omega) \exp \left[ -R^{(\text{inc})}_{nm}(\omega)z \right] \right] v_{x}(x) v_{n}(y)
\]

\[
H^{(\text{pol})}_{x}(x, y, z, \omega) = \sum_{n, m \in \mathbb{Z}} \left[ C^{(\text{pol})}_{nm}(\omega) \exp \left[ R^{(\text{pol})}_{nm}(\omega)z \right] + D^{(\text{pol})}_{nm}(\omega) \exp \left[ -R^{(\text{pol})}_{nm}(\omega)z \right] \right] v_{x}(x) w_{n}(y)
\]

\[
H^{(\text{inc})}_{y}(x, y, z, \omega) = \sum_{n, m \in \mathbb{Z}} \left[ \frac{1}{R^{(\text{inc})}_{nm}} \left[ k_{x} A^{(\text{inc})}_{nm}(\omega) + k_{y} C^{(\text{pol})}_{nm}(\omega) \right] \exp \left[ R^{(\text{inc})}_{nm}(\omega)z \right] \\
- \left[ k_{x} B^{(\text{inc})}_{nm}(\omega) + k_{y} D^{(\text{pol})}_{nm}(\omega) \right] \exp \left[ -R^{(\text{inc})}_{nm}(\omega)z \right] \right] v_{y}(x) v_{n}(y)
\]

\[
E^{(\text{inc})}_{x}(x, y, z, \omega) = \frac{i \omega \mu_{0}}{\gamma_{y}^{2}} \sum_{n, m \in \mathbb{Z}} \sum_{l, m \in \mathbb{Z}} R^{(\text{inc})}_{lm} \left[ (k_{x} + k_{y}) C^{(\text{pol})}_{nm}(\omega) - (k_{x} + k_{y}) D^{(\text{pol})}_{nm}(\omega) \right] \exp \left[ R^{(\text{inc})}_{nm}(\omega)z \right] \\
- \left[ k_{x} A^{(\text{inc})}_{nm}(\omega) - k_{y} C^{(\text{pol})}_{nm}(\omega) \right] \exp \left[ -R^{(\text{inc})}_{nm}(\omega)z \right] v_{x}(x) w_{n}(y)
\]

\[
E^{(\text{pol})}_{y}(x, y, z, \omega) = \frac{i \omega \mu_{0}}{\gamma_{y}^{2}} \sum_{n, m \in \mathbb{Z}} \sum_{l, m \in \mathbb{Z}} R^{(\text{pol})}_{lm} \left[ (k_{x} + k_{y}) A^{(\text{inc})}_{nm}(\omega) - (k_{x} + k_{y}) B^{(\text{inc})}_{nm}(\omega) \right] \exp \left[ R^{(\text{pol})}_{nm}(\omega)z \right] \\
- \left[ k_{x} D^{(\text{pol})}_{nm}(\omega) - k_{y} A^{(\text{inc})}_{nm}(\omega) \right] \exp \left[ -R^{(\text{pol})}_{nm}(\omega)z \right] w_{x}(x) v_{n}(y)
\]

where \(\gamma_{y}^{2} = -(\omega/c)^{2}\), \(\gamma_{x}^{2} = i \omega \mu_{0} (\sigma_{x} + i \omega \varepsilon_{x})\), for \(1 \leq n \leq N\), \(k_{x} = 2 \pi / L_{x}\), \(k_{y} = 2 \pi / L_{y}\), \(R^{(\text{inc})}_{nm} = k_{x}^{2} + k_{y}^{2} + \gamma_{x}^{2}\), and

\[
v_{x}(x) = \begin{cases} \cos(k_{x}x) & \text{if } l \leq 0 \\ \sin(k_{x}x) & \text{if } l > 0 \end{cases}
\]

\[
v_{y}(y) = \begin{cases} \cos(k_{y}y) & \text{if } m \leq 0 \\ \sin(k_{y}y) & \text{if } m > 0 \end{cases}
\]

A\(_{\text{inc}}\), B\(_{\text{inc}}\), C\(_{\text{pol}}\) and D\(_{\text{pol}}\) are complex coefficients that depend on frequency \(\omega\). B\(_{\text{inc}}\) and D\(_{\text{pol}}\) define the incident fields and A\(_{\text{inc}}\) and C\(_{\text{pol}}\) the reflected ones. B\(_{\text{inc}}\) and D\(_{\text{pol}}\) correspond to \(\vec{H}^{(\text{inc})}\) \(B_{\text{inc}}^{(\text{inc})}\) with \(l \geq 0\) and \(m \leq 0\), and \(D_{\text{pol}}^{(\text{pol})}\) with \(l > 0\) and \(m < 0\), generate \(\vec{H}^{(\text{inc})}\) \(B_{\text{inc}}^{(\text{pol})}\) with \(l < 0\) and \(m > 0\), and \(D_{\text{pol}}^{(\text{pol})}\) with \(l \leq 0\) and \(m \geq 0\), generate \(\vec{H}^{(\text{pol})}\). These fields are of the form:

\[
H^{(\text{inc})}_{x}(x, y, z, \omega) = \sum_{l=0, m=0} R_{lm}^{(\text{inc})}(\omega) \exp \left[ -R_{lm}^{(\text{inc})}(\omega)z \right] \cos(k_{x}x) \cos(k_{y}y)
\]

\[
H^{(\text{pol})}_{y}(x, y, z, \omega) = - \sum_{l=0, m=0} D_{lm}^{(\text{pol})}(\omega) \exp \left[ -R_{lm}^{(\text{pol})}(\omega)z \right] \sin(k_{x}x) \sin(k_{y}y)
\]

\[
H^{(\text{pol})}_{x}(x, y, z, \omega) = - \sum_{l=0, m=0} \frac{1}{B_{lm}^{(\text{pol})}} \left[ k_{x} B_{lm}^{(\text{pol})}(\omega) + k_{y} D_{lm}^{(\text{pol})}(\omega) \right] \exp \left[ -R_{lm}^{(\text{pol})}(\omega)z \right] \sin(k_{x}x) \cos(k_{y}y)
\]

\(© 2003\) RAS, GJI, 155, 623–640
\[ H_1^{\text{ex}(2)}(x, y, z, \omega) = - \sum_{l,m > 0} B_{lm}^{(0)}(\omega) \exp \left[ -R_{lm}(\omega)z \right] \sin(k_l x) \sin(k_m y) \]  
(18)

\[ H_2^{\text{ex}(2)}(x, y, z, \omega) = \sum_{l,m > 0} D_{lm}^{(0)}(\omega) \exp \left[ -R_{lm}(\omega)z \right] \cos(k_l x) \cos(k_m y) \]  
(19)

\[ H_1^{\text{ex}(2)}(x, y, z, \omega) = - \sum_{l,m > 0} \frac{1}{R_{lm}} \left[ k_{1l} B_{lm}^{(0)}(\omega) + k_{1m} D_{lm}^{(0)}(\omega) \right] \exp \left[ -R_{lm}(\omega)z \right] \cos(k_l x) \sin(k_m y). \]  
(20)

The remaining \( B_{lm}^{(0)} \) and \( D_{lm}^{(0)} \) are null.

It must be taken into account that Rayleigh scattering theory is an approximation valid when boundary slopes are not too large, because multiple reflections are not contemplated. In these cases, the series converge and then the coefficients corresponding to \(|l| \) or \(|m| \) greater than a finite value \( L \) can be neglected.

To obtain the electromagnetic response at the earth surface we apply the appropriate boundary conditions. These are the continuity of the tangential components of \( \vec{E} \) and \( \vec{H} \) on every interface. At \( z = 0 \), \( H_x, H_y, E_x \) and \( E_y \) are continuous; at \( z = S_n(x) \), for \( 1 \leq n \leq N - 1 \):

\[ H_n^{\text{in}}(x, y, S_n(x), \omega) + \frac{dS_n}{dx}(x)H_n^{\text{ex}}(x, y, S_n(x), \omega) = H_n^{\text{in}+1}(x, y, S_n(x), \omega) + \frac{dS_n}{dx}(x)H_n^{\text{ex}+1}(x, y, S_n(x), \omega) \]  
(21)

\[ H_n^{\text{in}}(x, y, S_n(x), \omega) = H_n^{\text{in}+1}(x, y, S_n(x), \omega) \]  
(22)

\[ E_n^{\text{in}}(x, y, S_n(x), \omega) + \frac{dS_n}{dx}(x)E_n^{\text{ex}}(x, y, S_n(x), \omega) = E_n^{\text{in}+1}(x, y, S_n(x), \omega) + \frac{dS_n}{dx}(x)E_n^{\text{ex}+1}(x, y, S_n(x), \omega) \]  
(23)

\[ E_n^{\text{in}}(x, y, S_n(x), \omega) = E_n^{\text{in}+1}(x, y, S_n(x), \omega). \]  
(24)

In the deepest medium, \( N, A_{lm}^{(N)} \) and \( C_{lm}^{(N)} \) are null for every \( l \) and \( m \) because the fields must not diverge as \( z \) increases.

When these conditions are applied, we find that the responses to \( \vec{H}_{\text{ext}(1)} \) and \( \vec{H}_{\text{ext}(2)} \) are uncoupled. This is a direct consequence of the imposed parity of the functions \( S_n(x) \). For the first external field, only the coefficients \( A_{lm}^{(e)} \) and \( B_{lm}^{(e)} \) corresponding to \( l \geq 0 \) and \( m \leq 0 \), and the coefficients \( C_{lm}^{(e)} \) and \( D_{lm}^{(e)} \) corresponding to \( l > 0 \) and \( m < 0 \), differ from 0. For the second one, the non-zero coefficients are \( A_{lm}^{(m)} \) and \( B_{lm}^{(m)} \) corresponding to \( l < 0 \) and \( m > 0 \) and \( C_{lm}^{(m)} \) and \( D_{lm}^{(m)} \) corresponding to \( l \leq 0 \) and \( m \geq 0 \).

Next, we calculate the response to \( \vec{H}_{\text{ext}(1)} \).

### 2.1 Response to \( \vec{H}_{\text{ext}(1)} \)

\( \vec{H}_{\text{ext}(1)} \) is defined by eqs (15)-(17). The continuity of \( H_x, H_y, E_x \) and \( E_y \) at \( z = 0 \) implies that, for every \( l \geq 0 \) and \( m \leq 0 \):

\[ A_{lm}^{(0)} + B_{lm}^{(0)} = A_{lm}^{(1)} + B_{lm}^{(1)}(\omega) \]  
(25)

for every \( l > 0 \) and \( m < 0 \),

\[ C_{lm}^{(0)} + D_{lm}^{(0)} = C_{lm}^{(1)} + D_{lm}^{(1)}(\omega) \]

\[ \frac{1}{\gamma_0 \gamma_1 R_{lm}} \left[ k_{1l} k_{1m} \left[ A_{lm}^{(0)}(\omega) - B_{lm}^{(0)}(\omega) \right] - (k_{1l}^2 + \gamma_1^2) \left[ C_{lm}^{(0)}(\omega) - D_{lm}^{(0)}(\omega) \right] \right] \]

\[ = \frac{1}{\gamma_0 \gamma_1 R_{lm}} \left[ k_{1l} k_{1m} \left[ A_{lm}^{(1)}(\omega) - B_{lm}^{(1)}(\omega) \right] - (k_{1l}^2 + \gamma_1^2) \left[ C_{lm}^{(1)}(\omega) - D_{lm}^{(1)}(\omega) \right] \right] \]

and, for every \( l \geq 0 \) and \( m \leq 0 \),

\[ \frac{1}{\gamma_0 \gamma_1 R_{lm}} \left[ (k_{1l}^2 + \gamma_1^2) \left[ A_{lm}^{(0)}(\omega) - B_{lm}^{(0)}(\omega) \right] - k_{1l} k_{1m} \left[ C_{lm}^{(0)}(\omega) - D_{lm}^{(0)}(\omega) \right] \right] \]

\[ = \frac{1}{\gamma_0 \gamma_1 R_{lm}} \left[ (k_{1l}^2 + \gamma_1^2) \left[ A_{lm}^{(1)}(\omega) - B_{lm}^{(1)}(\omega) \right] - k_{1l} k_{1m} \left[ C_{lm}^{(1)}(\omega) - D_{lm}^{(1)}(\omega) \right] \right]. \]

© 2003 RAS, GJI, 155, 623–640
At \( z = S_n(x) \), for \( 1 \leq n \leq N - 1 \), from eq. (21), for every \( m \leq 0 \):

\[
\sum_{l=0}^{\infty} \left[ A_{lm}^{(n)}(\omega) \exp \left( R_{lm}^{(n)} S_n(x) \right) + B_{lm}^{(n)}(\omega) \exp \left( -R_{lm}^{(n)} S_n(x) \right) \right] \cos \left( k_{l,m} x \right) \\
+ \frac{dS_n(x)}{dx} \sum_{l=0}^{\infty} \frac{1}{R_{lm}^{(n+1)}} \left[ k_{l,m} A_{lm}^{(n+1)}(\omega) + k_{m,n} C_{lm}^{(n+1)}(\omega) \right] \exp \left( R_{lm}^{(n+1)} S_n(x) \right) \\
- \left[ k_{l,m} B_{lm}^{(n+1)}(\omega) + k_{m,n} D_{lm}^{(n+1)}(\omega) \right] \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \sin \left( k_{l,m} x \right)
\]

\[
= \sum_{l=0}^{\infty} \left[ A_{lm}^{(n+1)}(\omega) \exp \left( R_{lm}^{(n+1)} S_n(x) \right) + B_{lm}^{(n+1)}(\omega) \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \right] \cos \left( k_{l,m} x \right) \\
+ \frac{dS_n(x)}{dx} \sum_{l=0}^{\infty} \frac{1}{R_{lm}^{(n+1)}} \left[ k_{l,m} A_{lm}^{(n+1)}(\omega) + k_{m,n} C_{lm}^{(n+1)}(\omega) \right] \exp \left( R_{lm}^{(n+1)} S_n(x) \right) \\
- \left[ k_{l,m} B_{lm}^{(n+1)}(\omega) + k_{m,n} D_{lm}^{(n+1)}(\omega) \right] \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \sin \left( k_{l,m} x \right)
\]

From eqs (22) and (23), for every \( m < 0 \):

\[
\sum_{l=0}^{\infty} \left[ C_{lm}^{(n)}(\omega) \exp \left( R_{lm}^{(n)} S_n(x) \right) + D_{lm}^{(n)}(\omega) \exp \left( -R_{lm}^{(n)} S_n(x) n \right) \right] \sin \left( k_{l,m} x \right)
\]

\[
= \sum_{l=0}^{\infty} \left[ C_{lm}^{(n+1)}(\omega) \exp \left( R_{lm}^{(n+1)} S_n(x) \right) + D_{lm}^{(n+1)}(\omega) \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \right] \sin \left( k_{l,m} x \right)
\]

\[
= \frac{1}{\nu_{l,m}} \sum_{l=0}^{\infty} \frac{1}{R_{lm}^{(n+1)}} \left[ k_{l,m} A_{lm}^{(n+1)}(\omega) - (k_{l,m} + \nu_{l,m}) C_{lm}^{(n+1)}(\omega) \right] \exp \left( R_{lm}^{(n+1)} S_n(x) \right) \\
- \left[ k_{l,m} D_{lm}^{(n+1)}(\omega) - (k_{l,m} + \nu_{l,m}) B_{lm}^{(n+1)}(\omega) \right] \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \sin \left( k_{l,m} x \right)
\]

\[
= \frac{1}{\nu_{l,m}} \sum_{l=0}^{\infty} \frac{1}{R_{lm}^{(n+1)}} \left[ k_{l,m} A_{lm}^{(n+1)}(\omega) - (k_{l,m} + \nu_{l,m}) C_{lm}^{(n+1)}(\omega) \right] \exp \left( R_{lm}^{(n+1)} S_n(x) \right) \\
- \left[ k_{l,m} D_{lm}^{(n+1)}(\omega) - (k_{l,m} + \nu_{l,m}) B_{lm}^{(n+1)}(\omega) \right] \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \sin \left( k_{l,m} x \right)
\]

respectively. By the last, from eq. (24), for every \( m \leq 0 \):

\[
\frac{1}{\nu_{l,m}} \sum_{l=0}^{\infty} \frac{1}{R_{lm}^{(n+1)}} \left[ (k_{l,m} + \nu_{l,m}) A_{lm}^{(n+1)}(\omega) - k_{l,m} D_{lm}^{(n+1)}(\omega) \right] \exp \left( R_{lm}^{(n+1)} S_n(x) \right) \\
- \left[ (k_{l,m} + \nu_{l,m}) B_{lm}^{(n+1)}(\omega) - k_{l,m} C_{lm}^{(n+1)}(\omega) \right] \exp \left( -R_{lm}^{(n+1)} S_n(x) \right) \cos \left( k_{l,m} x \right)
\]

Multiplying eqs (29) and (32) by \( \cos \left( k_{l,m} x \right) \) for every integer number \( i \) between 0 and \( L \), eqs (30) and (31) by \( \sin \left( k_{l,m} x \right) \) for every \( i \) between 1 and \( L \), and then integrating \( x \) between \(-\lambda_x/2\) and \( \lambda_x/2\), we obtain systems of linear equations independent of \( x \) that can be solved independently for every \( m \). We calculate the coefficients \( A_{lm}^{(n_{\lambda_x})}, B_{lm}^{(n_{\lambda_x})}, C_{lm}^{(n_{\lambda_x})} \) and \( D_{lm}^{(n_{\lambda_x})} \) that define the electromagnetic response at the Earth's surface using a procedure similar to that described in previous works (Osella & Martinelli 1993; Martinelli & Osella 1997). The RF method proposed in these papers were extensively tested by comparison to FD, FE or IE solutions. There, a self-consistency criterion for the determination of the validity of Rayleigh's approximation in each particular case was established, which is also valid for the method presented here. When the
approximation is valid, the series expansion of field components converge, and the root mean squared values of the residual discontinuities of the tangential components at layer boundaries can be reduced to a level below a few per cent by increasing the number of scattering orders, \( L \). In contrast, when the approximation is no longer valid, the residual discontinuities remain large, and the series directly exhibit an oscillatory behaviour, or they converge for small values of \( L \) and then become divergent as \( L \) increases. The maximum boundary slopes that can be correctly modelled using RF techniques lie typically in the range \( 50^\circ \text{–} 60^\circ \), but can exceed these values in very resistive cases.

2.2 Response to \( \vec{H}^{(\text{ext})} \)

In this case, the external field is defined by eqs (18)–(20). The continuity of the tangential components of \( \vec{H} \) and \( \vec{E} \), at \( z = 0 \), implies that eqs (25) and (28) are valid, for every \( l < 0 \) and \( m > 0 \), and eqs (26) and (27), for every \( l \leq 0 \) and \( m \geq 0 \). At \( z = S_n(x) \), with \( 1 \leq n \leq N - 1 \), eqs (29) and (32) are satisfied for every \( m > 0 \), and eqs (30) and (31), for every \( m \geq 0 \), though here, the sums in eqs (29) and (32) extend over the indices \( l < 0 \), and the sums in eqs (30) and (31) over the indices \( l \leq 0 \). Now, we multiply eqs (29) and (32) by \( \sin(\kappa x) \) for every \( i \) between \(-L\) and \(-1\) and eqs (30) and (31) by \( \cos(\kappa x) \) for every \( i \) between \(-L\) and \( 0 \), and then we integrate \( x \) between \(-\lambda_s/2\) and \( \lambda_s/2 \). Once again, we obtain systems of linear equations that can be solved independently for every \( m \).

2.3 Model extension

The studied area is located between \( x_{\text{min}} \) and \( x_{\text{max}} \) such that \( x_{\text{max}} - x_{\text{min}} = L_x \), and \( y_{\text{min}} \) and \( y_{\text{max}} \) such that \( y_{\text{max}} - y_{\text{min}} = L_y \). Since, in general, \( S_n(x_{\text{max}}) \) is different from \( S_n(x_{\text{min}}) \), it is not possible to obtain a periodic function of \( x \) simply by extending \( S_n \) to the left and to the right as the constant values \( S_n(x_{\text{min}}) \) and \( S_n(x_{\text{max}}) \), respectively. Because of this, we instead centre the model at \( x = \lambda_s/4 \), and assume that

\[
\begin{align*}
S_n(x) &= \begin{cases} 
S_n(x_{\text{min}}) & \text{if } 0 \leq x \leq x_{\text{min}} \\
S_n(x_{\text{max}}) & \text{if } x_{\text{max}} \leq x \leq \lambda_s/2 \\
S_n(-x) & \text{if } -\lambda_s/2 \leq x \leq 0 
\end{cases} 
\end{align*}
\tag{32}
\]

with \( x_{\text{min}} = \lambda_s/4 - L_x/2 \) and \( x_{\text{max}} = \lambda_s/4 + L_x/2 \). It is important to note that this extension of the interfaces does not impose any restriction on the type of functions \( S_n(x) \) that can be considered inside the studied area. Furthermore, assuming that \( S_n \) is an even function of \( x \) greatly simplifies the treatment for reasons that are explained later in this section.

To calculate the coefficients \( B_{lm} \) and \( D_{lm} \), we must select convenient extensions of \( H_x^{(\text{ext})} \) and \( H_y^{(\text{ext})} \) at \( z = 0 \). This is a more complex problem than the extension of the boundaries \( S_n(x) \). First, we show how we extend these components, for periods such that the quasi-stationary approximation is valid in the air. In this approximation,

\[
\vec{V} \times H_0 = \vec{V} \times \vec{H}^{(\text{ext})} = \vec{V} \times \vec{H}^{(\text{ind})} = 0,
\tag{33}
\]

where \( \vec{H}^{(\text{ind})} \) is the induced magnetic field. Then,

\[
\partial_t H_x^{(\text{ext})} - \partial_y H_y^{(\text{ext})} = 0.
\tag{34}
\]

We are modelling the response to an external field that in a certain region is 3-D; there \( \partial_x H_x^{(\text{ext})} \) and \( \partial_y H_y^{(\text{ext})} \) and are not null. We select the area to be studied such that it completely contains this region and assume that outside there \( \partial_x H_x^{(\text{ext})} \) and \( \partial_y H_y^{(\text{ext})} \) are null (this means that \( H_x^{(\text{ext})} \) does not depend on \( y \) and \( H_y^{(\text{ext})} \) does not depend on \( x \)). Then, at the surface of the earth, \( H_x^{(\text{ext})} \) must be constant at the borders of the studied area that correspond to \( y = y_{\text{min}} \) of \( y = y_{\text{max}} \), while \( H_y^{(\text{ext})} \) must be constant at the borders \( x = x_{\text{min}} \) and \( x = x_{\text{max}} \). In general, \( H_x^{(\text{ext})} \), which is a function of \( x \), and \( H_y^{(\text{ext})} \), which is a constant, are different at the borders \( y = y_{\text{min}} \) and \( y = y_{\text{max}} \). Analogously, \( H_y^{(\text{ext})} \), which in this case is a constant, and \( H_x^{(\text{ext})} \), a function of \( y \), are also different at the borders \( x = x_{\text{min}} \) and \( x = x_{\text{max}} \). Considering this, we centre the model at \( (x, y) = (\lambda_s/2, \lambda_s/2) \), and extend these components to the area \( 0 \leq x \leq \lambda_s/2, 0 \leq y \leq \lambda_s/2 \), as follows:

\[
H_x^{(\text{ext})}(x, y_{\text{min}}, 0, \omega) = \begin{cases} 
H_x^{(\text{ext})}(x, 0, \omega) & \text{if } x_{\text{min}} \leq x \leq x_{\text{max}}, 0 \leq y \leq y_{\text{min}} \\
H_x^{(\text{ext})}(x, y_{\text{max}}, 0, \omega) & \text{if } x_{\text{min}} \leq x \leq x_{\text{max}}, y_{\text{max}} \leq y \leq y_{\text{min}} \\
H_x^{(\text{ext})}(x_{\text{min}}, y_{\text{min}}, 0, \omega) & \text{if } 0 \leq x \leq x_{\text{min}}, 0 \leq y \leq \lambda_s/2 \\
H_x^{(\text{ext})}(x_{\text{max}}, y_{\text{min}}, 0, \omega) & \text{if } 0 \leq x \leq x_{\text{max}}, y_{\text{max}} \leq y \leq \lambda_s/2 \\
H_x^{(\text{ext})}(x, y_{\text{max}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, 0 \leq y \leq \lambda_s/2 \\
H_x^{(\text{ext})}(x_{\text{min}}, y_{\text{max}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, y_{\text{min}} \leq y \leq y_{\text{max}} \\
H_x^{(\text{ext})}(x_{\text{max}}, y_{\text{max}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, y_{\text{min}} \leq y \leq y_{\text{max}} \\
\end{cases}
\tag{35}
\]

\[
H_y^{(\text{ext})}(x_{\text{min}}, y_{\text{min}}, 0, \omega) = \begin{cases} 
H_y^{(\text{ext})}(x_{\text{max}}, y_{\text{min}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, 0 \leq y \leq y_{\text{min}} \\
H_y^{(\text{ext})}(x_{\text{min}}, y_{\text{max}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, y_{\text{max}} \leq y \leq y_{\text{min}} \\
H_y^{(\text{ext})}(x_{\text{max}}, y_{\text{max}}, 0, \omega) & \text{if } 0 \leq x \leq \lambda_s/2, y_{\text{min}} \leq y \leq y_{\text{max}} \\
\end{cases}
\tag{36}
\]

© 2003 RAS, GJI, 155, 623–640
The simplest form to extend these components to the whole area \(-\lambda_x/2 \leq x \leq \lambda_x/2, -\lambda_y/2 \leq y \leq \lambda_y/2\), considering that they usually are not null at the coordinate axes, would be to assume that the extended \(H^{(\text{ext})}\) is such that \(H^{(\text{ext})}_x\) and \(H^{(\text{ext})}_y\) are even functions of \(x\) and \(y\). As this is not compatible with eq. (35), we instead suppose that each one is the sum of both an even and an odd function of \(x\) and \(y\). This corresponds to assuming that
\[
\vec{H}^{(\text{ext})} = \vec{H}^{(\text{ext1})} + \vec{H}^{(\text{ext2})},
\]
where \(\vec{H}^{(\text{ext1})}\) and \(\vec{H}^{(\text{ext2})}\) are the fields defined by eqs (15)–(17) and (18)–(20), respectively. We show next that this assumption unequivocally defines the extensions of \(H^{(\text{ext})}_x\) and \(H^{(\text{ext})}_y\) to the area \(-\lambda_x/2 \leq x \leq \lambda_x/2, -\lambda_y/2 \leq y \leq \lambda_y/2\). The selected extension is advantageous because, as we have formerly pointed out, \(H^{(\text{ext1})}\) and \(H^{(\text{ext2})}\) give uncoupled responses when the boundaries \(S_0\) are even functions of \(x\), and does not restrict the fields \(H^{(\text{ext})}\) that can be considered in the studied area.

For the extended fields in the air, given by eqs (5)–(10) with \(n = 0\), the quasi-stationary approximation corresponds to taking the limits \(y_0 \approx 0\) and \(R^0_{\text{ao}} z \ll 1\). Then,
\[
A^0_{00} = B^0_{00} \tag{38}
\]
\[
C^0_{00} = D^0_{00} \tag{39}
\]
\[
A^0_{lm} = B^0_{lm} = 0 \quad \text{if} \quad m \neq 0 \tag{40}
\]
\[
C^0_{lm} = D^0_{lm} = 0 \quad \text{if} \quad l \neq 0 \tag{41}
\]
\[
k_{lm} A^0_{lm} = k_x C^0_{lm} \quad \text{if} \quad l \neq 0 \quad \text{and} \quad m \neq 0 \tag{42}
\]
\[
k_{lm} B^0_{lm} = k_y D^0_{lm} \quad \text{if} \quad l \neq 0 \quad \text{and} \quad m \neq 0 \tag{43}
\]
because, the electric field must not diverge. This hypothesis is stronger than eq. (34) and ensures its validity. Using eq. (34) alone, relations (41)–(44) could also be obtained but \(A^0_{00}\) and \(C^0_{00}\) could not be determined. Replacing relations (41)–(44) into eqs (15)–(20), we obtain that
\[
H^{(\text{ext})}_x(x, y, z, \omega) = B^{(0)}_{00}(\omega) + \sum_{l=0, m \geq 0} B^{(0)}_{lm}(\omega) \exp[-k_{lm} S_0 x] \cos(k_x x) \cos(k_y y) \tag{44}
\]
\[
H^{(\text{ext})}_y(x, y, z, \omega) = - \sum_{l=0, m \geq 0} \frac{k_{lm}}{k_x} B^{(0)}_{lm}(\omega) \exp[-k_{lm} S_0 x] \sin(k_x x) \sin(k_y y) \tag{45}
\]
\[
H^{(\text{ext2})}_x(x, y, z, \omega) = - \sum_{l=0, m \geq 0} \frac{k_{lm}}{k_y} D^{(0)}_{lm}(\omega) \exp[-k_{lm} S_0 x] \cos(k_x x) \sin(k_y y) \tag{46}
\]
\[
H^{(\text{ext2})}_y(x, y, z, \omega) = D^{(0)}_{00}(\omega) + \sum_{l=0, m \geq 0} D^{(0)}_{lm}(\omega) \exp[-k_{lm} S_0 x] \cos(k_x x) \cos(k_y y) \tag{48}
\]
\[
H^{(\text{ext2})}_x(x, y, z, \omega) = - \sum_{l=0, m \geq 0} \frac{k_{lm}}{k_y} D^{(0)}_{lm}(\omega) \exp[-k_{lm} S_0 x] \cos(k_x x) \sin(k_y y) \tag{49}
\]
where \(k_{lm} = \sqrt{k_x^2 + k_y^2}\). So, in this approximation, \(H^{(\text{ext1})}\) is determined only by the coefficients \(B^{(0)}_{lm}\) and \(B^{(0)}_{lm}\) with \(l > 0\) and \(m \leq 0\) or by the function \(H^{(\text{ext1})}_x(x, y, 0, \omega)\), and \(H^{(\text{ext2})}\) only by \(D^{(0)}_{00}\) and \(D^{(0)}_{lm}\) with \(l \leq 0\) and \(m > 0\) or by \(H^{(\text{ext2})}_x(x, y, 0, \omega)\). Then, considering eq. (38), \(H^{(\text{ext})}\) at \(z = 0\), is given by
\[
H^{(\text{ext})}_x(x, y, 0, \omega) = B^{(0)}_{00}(\omega) + \sum_{l=0, m \geq 0} B^{(0)}_{lm}(\omega) \cos(k_x x) \cos(k_y y) \tag{50}
\]
\[
H^{(\text{ext})}_y(x, y, 0, \omega) = - \sum_{l=0, m \geq 0} \frac{k_{lm}}{k_x} B^{(0)}_{lm}(\omega) \sin(k_x x) \sin(k_y y) + D^{(0)}_{00}(\omega) \tag{51}
\]
\[
H^{(\text{ext})}_x(x, y, 0, \omega) = - \sum_{l=0, m \leq 0} \frac{k_{lm}}{k_x} B^{(0)}_{lm}(\omega) \sin(k_x x) \sin(k_y y) \tag{52}
\]
\[
+ \sum_{l \geq 0, m \geq 0} D^{(0)}_{lm}(\omega) \cos(k_x x) \cos(k_y y) \tag{51}
\]
\[
H^{(\text{ext})}_x(x, y, 0, \omega) = - \sum_{l=0, m \leq 0} \frac{k_{lm}}{k_x} B^{(0)}_{lm}(\omega) \sin(k_x x) \cos(k_y y) \tag{52}
\]
\[
- \sum_{l \geq 0, m \geq 0} k_{lm} D^{(0)}_{lm}(\omega) \cos(k_x x) \sin(k_y y). \tag{52}
\]
Multiplying $H_x^{\text{ext}}(x, y, 0, \omega)$ by $\cos(k_x x) \cos(k_y y)$, for $(i, j) = (0, 0)$ and for every $(i, j)$ with $0 < i \leq L$ and $-L \leq j < 0$, and $H_y^{\text{ext}}(x, y, 0, \omega)$ by $\cos(k_x x) \cos(k_y y)$, for $(i, j) = (0, 0)$ and for every $(i, j)$ with $-L \leq i \leq 0$ and $0 < j \leq L$, and then integrating $x$ and $y$ over the area $0 \leq x \leq \lambda_x / 2$, $0 \leq y \leq \lambda_y / 2$, we obtain a system of $2(L+1) + 1$ linear equations that allows us to calculate the coefficients.

For periods such that the problem is not quasi-stationary, the restrictions imposed by eqs (35) and (41)-(44) are not present. Then, we simply extend $H_x^{\text{ext}}$ and $H_y^{\text{ext}}$ to the area $0 \leq x \leq \lambda_x / 2$, $0 \leq y \leq \lambda_y / 2$, as follows:

$$H_x^{\text{ext}}(x, y, 0, \omega) = \begin{cases} H_x(x, y, \min, 0, \omega) & \text{if } x_{\min} \leq x \leq x_{\max}, 0 \leq y \leq y_{\min} \\ H_x(x, y, \max, 0, \omega) & \text{if } x_{\min} \leq x \leq x_{\max}, y_{\max} \leq y \leq y_{\max} \\ H_x(x, y, \min, y, 0, \omega) & \text{if } 0 \leq x \leq x_{\max}, 0 \leq y \leq y_{\min} \\ H_x(x, y, \max, y, 0, \omega) & \text{if } 0 \leq x \leq x_{\max}, y_{\min} \leq y \leq y_{\max} \end{cases}$$

$$H_y^{\text{ext}}(x, y, 0, \omega) = \begin{cases} H_y(x, y, \min, 0, \omega) & \text{if } x_{\min} \leq x \leq x_{\max}, 0 \leq y \leq y_{\min} \\ H_y(x, y, \max, 0, \omega) & \text{if } x_{\min} \leq x \leq x_{\max}, y_{\max} \leq y \leq y_{\max} \\ H_y(x, y, \min, y, 0, \omega) & \text{if } 0 \leq x \leq x_{\max}, 0 \leq y \leq y_{\min} \\ H_y(x, y, \max, y, 0, \omega) & \text{if } 0 \leq x \leq x_{\max}, y_{\min} \leq y \leq y_{\max} \end{cases}$$

where $\tau$ denotes the $x$ or $y$ components of $\vec{H}^{\text{ext}}$ and assume, without lose of generality, that both components are even functions of $x$ and $y$.

This condition is satisfied when $\bar{y}$ eqs (5)–(10) is given by the sum of two terms, one depending only on the coefficients of $-\lambda^2 V_x y$ and $-\lambda^2 V_y x$ generate, respectively, the TE and TM modes.

$$H_x(x, y, 0, \omega) = H_{x,\max}(x, y, 0, \omega) + H_{x,\min}(x, y, 0, \omega)$$

$$H_y(x, y, 0, \omega) = H_{y,\max}(x, y, 0, \omega) + H_{y,\min}(x, y, 0, \omega)$$

The following relations can be written as

$$\vec{H}_{\text{ext}}(x, y, 0, \omega) = \vec{H}_x(x, y, 0, \omega)$$

$$\vec{H}_{\text{ext}}(x, y, 0, \omega) = \vec{H}_y(x, y, 0, \omega)$$

$$\vec{E}_{\text{ext}}(x, y, 0, \omega) = \vec{E}_x(x, y, 0, \omega)$$

$$\vec{E}_{\text{ext}}(x, y, 0, \omega) = \vec{E}_y(x, y, 0, \omega)$$

where $\vec{H}$ and $\vec{E}$ are tensors of dimension $(2 \times 2)$, and $\tilde{\sigma}$ is a file vector of dimension two. $\eta_x, \eta_y, \theta_x, \xi_x$, and $\xi_y$ depend on $H_x^{\text{ext}}(x, y, 0, \omega)$, and $\eta_x, \eta_y, \theta_y, \xi_x$, and $\xi_y$ depend on $H_y^{\text{ext}}(x, y, 0, \omega)$. Then, $\tilde{Z}$ and $\tilde{T}$ are given by...

© 2003 RAS, GJI, 155, 623–640
Figure 2. 2-D electrical model proposed to represent the kind of resistivity distribution that could be found at coastlines.

\[
\bar{Z}(x, y, \omega) = \bar{\xi}(x, y, \omega)\bar{H}^{-1}(x, y, \omega) \tag{60}
\]

\[
\bar{F}(x, y, \omega) = \bar{\delta}(x, y, \omega)\bar{H}^{-1}(x, y, \omega). \tag{61}
\]

When \(\bar{H}^{(ext)1}\) is non-uniform and \(\bar{H}^{(ext)2}\) is uniform, only \(Z_{xx}, Z_{yx}\) and \(T_{y}\) contain source effects. These magnitudes constitute generalizations of the MT TE responses. Conversely, when \(\bar{H}^{(ext)1}\) is uniform and \(\bar{H}^{(ext)2}\) is non-uniform, source effects are present only in \(Z_{xx}, Z_{yx}\) and \(T_{y}\), which in this case are generalizations of the MT TM responses.

As has been stated previously, the uniform source hypothesis used for MT interpretation has proved to work well in a great number of studies, especially those carried out at mid latitudes, and for periods not exceeding 1000s, approximately. Nevertheless, at low or high latitudes, and for hourly or greater periods, this hypothesis usually fails, and then the electrical models obtained assuming 1-D external fields contain source distortions. In the following section we study how source distortions affect the responses at coastlines by comparison with the results obtained for 1-D sources.

4 APPLICATION: SOURCE EFFECTS AT COASTLINES

For this study we select a 2-D electrical model that can be considered representative of this kind of tectonic environment. This model is shown in Fig. 2. The upper layer corresponds to the ocean, the second one to the continental upper crust, the more conductive third one to the continental lower crust and to the oceanic crust, the fourth one to the lithospheric mantle and the deeper one to the beginning of the asthenosphere. We have analysed the responses of this structure to 1-D and different 2-D and 3-D, external fields, for a wide range of periods, arriving at the conclusion that source effects begin to be noticeable for periods greater than approximately 6 h and become larger as the period increases. Considering this and in order to not excessively increase the length of this paper, in this section we only present the responses obtained at a period of 24 h.

4.1 1-D, 2-D and 3-D \(\bar{H}^{(ext)}\)—uniform \(\bar{H}^{(ext)2}\)

As we explained in the previous section, if \(\bar{H}^{(ext)1}\) is 1-D, only the \(xx\) and \(yx\) components of \(\bar{Z}\) (and the corresponding apparent resistivities \(\rho_{xx}\) and \(\rho_{yx}\), and phases \(\phi_{xx}\) and \(\phi_{yx}\)) and \(T_{y}\) can contain source effects, which depend on the morphology of \(\bar{H}^{(ext)1}\). In particular, if \(\bar{H}^{(ext)1}\) is also 1-D, \(\rho_{xx}\) and \(\phi_{xx}\) are null, and \(\rho_{yx}, \phi_{yx}\), and \(T_{y}\) are the MT TE mode responses. In this case \(\bar{H}^{(ext)1}\) is polarized in the \(x\) direction and has only one non-null coefficient: \(B_{00}(0)\).

The MT TE responses of the model shown in Fig. 2 are displayed in Fig. 3. \(\rho_{xx}\) and \(\phi_{xx}\) exhibit low variation ranges, between 8 and 15 \(\Omega\) m and 38° and 54°, respectively. The maximum magnitude of \(T_{y}\) is about 0.18.

Now, we consider two different 2-D external fields \(\bar{H}^{(ext)}\) with strike direction \(y\), \(\bar{H}^{(ext)1}\) 2-D+ (shown in Figs 4a and b) and \(\bar{H}^{(ext)2}\) 2-D− (shown in Figs 4c and d). The anomalous zones of both fields have characteristic widths similar to that of the equatorial electrojet (1000 km, approximately), and are centred just over the structure. In fact, \(\bar{H}^{(ext)1}\) 2-D+ is a simplified representation of the field that would produce an equatorial electrojet oriented in the \(y\) direction. \(\bar{H}^{(ext)2}\) 2-D− has a somewhat more complex spatial dependence; in particular, its \(x\) component is null at two values of \(x\). For these fields, the non-null coefficients are only \(B_{0l}(0)\) for \(l \geq 0\). From eqs (45)–(47), it is seen that they are necessarily polarized in the \(x-z\) plane. Both \(x\) components can be normalized to one outside the anomalous zones without affecting the responses. Fig. 5 shows the response of the proposed model to the field \(\bar{H}^{(ext)1}\) 2-D+. Comparing with Fig. 3, the most remarkable fact is that \(\rho_{xx}\) is lower than in the former case, while \(\phi_{xx}\) is greater, below the centre of the anomalous field. In contrast, \(\rho_{yx}\) is greater and \(\phi_{yx}\) is lower, below both sides. The maximum value of the tipper is 0.77. Fig. 6 displays the response to the field 2-D−. The variations of \(\rho_{xx}\) and \(\phi_{xx}\) are much greater than in the former cases. Note the presence of two narrow high-resistivity and low-phase zones. They are located just over the lines where \(H_{zz}^{(ext)}\) is equal to zero. Along the left of these zones, tipper values are also much greater than those obtained for a 1-D source, reaching 14.

© 2003 RAS, GJI, 155, 623–640
Figure 3. Response of the model shown in Fig. 2 to a spatially uniform inducing field polarized in the x direction (MT TE mode response), at a period of 24 h.

The spatial dependence of the external fields can be much more complex, for example, in zones where auroral electrojets are present. These fields can be 3-D and can have varied morphologies. As a first approximation to this kind of situation, we also selected two 3-D $\vec{H}^{(ext)}$ fields, $\vec{H}^{(ext)}$ 3-D+ (shown in Fig. 7) and $\vec{H}^{(ext)}$ 3-D− (shown in Fig. 8). The anomalies of these fields have an areal extension of $1000 \times 1000$ km$^2$, and once again its x components are normalized to unity outside the anomalous zones. The response to the field $\vec{H}^{(ext)}$ 3-D+, at a period of 24 h is shown in Fig. 9. In this case a dependence of the response on the y coordinate appears that is purely a 3-D source effect. $\rho_{xy}$ and $\phi_{xy}$ variation ranges are similar to those obtained for the source $\vec{H}^{(ext)}$ 2-D+, although maximum $|T_x|$ values are greater. Fig. 10 displays the response to the field $\vec{H}^{(ext)}$ 3-D−. As in the response to the field $\vec{H}^{(ext)}$ 2-D−, two zones of very high resistivity and tipper magnitude appear where the values of $H^{(ext)}_x$ tend to zero. The difference is that in this case, these zones and those with lower values of $\phi_{xy}$ are not coincident. $\phi_{xy}$ has a wide variation range, almost between 0° and 90°. Comparing Fig. 3 to Figs 9 and 10, it is seen that the MT TE response of the 2-D structure is almost totally masked by 3-D source effects in the area located below the anomalies of the inducing fields.

4.2 Uniform $\vec{H}^{(ext)}$—1-D and 3-D $\vec{H}^{(ext)}$

When $\vec{H}^{(ext)}$ is 1-D, source effects can only appear in $\rho_{xx}$, $\rho_{yy}$, $\phi_{xx}$, $\phi_{yy}$, and $T_y$, and depend on the morphology of $\vec{H}^{(ext)}$. If $\vec{H}^{(ext)}$ is also 1-D, having only the coefficient $D^{(0)}_l$ different from 0 for $l \leq 0$. Then, according to eqs (18)–(20), it might be polarized along the y axis. It is well known that it is not possible to have such a 2-D external field in quasi-stationary cases. This is corroborated here by eqs (48)–(50). So, in the following we consider directly the case of 3-D $\vec{H}^{(ext)}$ fields.

We selected two $\vec{H}^{(ext)}$ fields, $\vec{H}^{(ext)}$ 3-D+ and $\vec{H}^{(ext)}$ 3-D−, which are similar to the fields $\vec{H}^{(ext)}$ 3-D+ and $\vec{H}^{(ext)}$ 3-D− proposed previously, but rotated by 90° (Figs 12 and 13, respectively). Fig. 14 shows the response to $\vec{H}^{(ext)}$ 3-D+. Comparing Fig. 14 with Fig. 11, a zone with lower resistivity and greater phase than for the uniform source is clearly observed, just below the central anomaly of the 3-D field. Additionally, values of $|T_y|$ different from 0 are found. They can reach up to 7. Fig. 15 plots the response to $\vec{H}^{(ext)}$ 3-D−. Once more, two narrow zones of very high resistivity and tipper values can be identified that in this case, coincide with the zones where $H^{(ext)}_y$ tends to zero. For both external fields, $\vec{H}^{(ext)}$ 3-D+ and $\vec{H}^{(ext)}$ 3-D−, source distortions of $\phi_{xy}$ are as important as the distortions observed in $\phi_{xy}$ for the
5 CONCLUSIONS

In the present work, we present a method for the calculation of the electromagnetic response of 2-D multilayered earth structures having smooth, irregular boundaries, to arbitrary, non-uniform, 2-D or 3-D external fields. This method is based on the application of a Rayleigh–Fourier technique and was obtained by extending previous MT 2-D and 3-D Rayleigh–Fourier modelling codes.

Applying this method, we made a theoretical investigation of the magnitude and characteristics of MT source effects at coastlines. We selected a 2-D electrical model with strike direction $\gamma$, which can be considered representative of this kind of tectonic region, and we calculated the response of this model, $\bar{Z}$ and $\bar{T}$, at the Earth’s surface to different spatially non-uniform 2-D and 3-D inducing fields, over a broad range of periods. We evaluated source effects by comparing these responses with those obtained for 1-D sources. The spatial dependence of the fields produced, for example, by equatorial and auroral electrojets, as well as the source effects produced by these fields on 2-D structures, can be highly complex. As a first approximation to this problem, and in order to obtain general conclusions concerning the main and more basic characteristics of these effects, we selected geometries of the external fields, which are relatively simple, but contain several of the more important and typical features found in practice. We let the spatial dependence of each selected source be fixed and varied only its period. Nevertheless, it must be taken into account that the spatial dependence of actual sources depends on the period. In all of the studied cases, we found that source effects begin to be detectable for periods greater than approximately 6 h, and increase with period. At a period of 24 h, they are very important, as has been shown in the previous section. For each particular source, the zones in which the different components of the response are enhanced or decreased, do not change with period.

As is well known, for uniform sources and 2-D structures with strike direction $\gamma$, $Z_{\gamma\gamma}$ and $T_{\gamma}$ are the MT TE mode responses and $Z_{\gamma\gamma}$ is the MT TM mode response, while $Z_{\gamma\gamma}$, $Z_{\gamma\gamma}$, and $T_{\gamma}$ are null. One relevant theoretical result of this work is that the 3-D non-uniform inducing field could be separated into two contributions, one that produces source effects only in $Z_{\gamma\gamma}$, $Z_{\gamma\gamma}$ and $T_{\gamma}$, and another that produces source effects only in $Z_{\gamma\gamma}$, $Z_{\gamma\gamma}$, and $T_{\gamma}$. Then, these magnitudes can be thought of as generalized TE and TM responses, respectively, although it is important to point out that they do not correspond strictly to TE and TM modes of propagation.

Figure 6. Response to the external field $\mathbf{H}^{(ext)}$ 2-D −.
Figure 7. Spatial dependence of the first 3-D $\vec{H}^{\text{ext1}}$ inducing field considered, $\vec{H}^{\text{ext1}}_{3-D+}$, at the Earth’s surface. This field has a harmonic time dependence with a period of 24 h. The $x$ component is an even function of $x$ and $y$, and its value outside the anomalous zone has been normalized to 1.

Figure 8. Spatial dependence of the second 3-D $\vec{H}^{\text{ext1}}$ inducing magnetic field considered, $\vec{H}^{\text{ext1}}_{3-D-}$, at the Earth’s surface. The $x$ component is an odd function of $x$ and $y$ plus a constant, and its value outside the anomalous zone has been normalized to 1.
Figure 9. Response to the external field $\vec{H}^{(ext)}$ 3-D+

Figure 10. Response to the external field $\vec{H}^{(ext)}$ 3-D−.
First, we considered external fields $\mathbf{H}^{\text{ext}}$ that produce source effects on the TE responses. The fields considered are 1-D far from the structure and near the structure have 2-D or 3-D anomalies. We found that when the anomaly of $H^{\text{ext}}_x$ is an even function of $x$ or an even function of $x$ and $y$, the values of $\rho_{yx}$ are lower than those obtained for 1-D sources, below the centre of the anomaly, while they are greater towards both sides. $\phi_{yx}$ follows the inverse behaviour. Variation ranges of these magnitudes are similar in both cases. On the other hand, if $H^{\text{ext}}_x$ is a constant plus an odd function of $x$ or an odd function of $x$ and $y$, narrow zones of high resistivity and $|T_x|$ are observed, where $H^{\text{ext}}_x$ tends to zero. There, the variation ranges of $\rho_{yx}$ and $|T_x|$ are almost an order of magnitude greater than those obtained for a 1-D source. The lower values of $\phi_{yx}$ are also reached at these zones in the 2-D− case, but not in the 3-D− case. In both cases, $\phi_{yx}$ varies almost between 0° and 90°.

Next, we analysed source effects on the TM responses. We considered two fields, $\mathbf{H}^{\text{ext}}_x$ 3-D+ and $\mathbf{H}^{\text{ext}}_x$ 3-D−, which were obtained by rotating 90° $\mathbf{H}^{\text{ext}}_x$ 3-D+ and $\mathbf{H}^{\text{ext}}_x$ 3-D−, respectively. Then the anomaly of the $y$ component of $\mathbf{H}^{\text{ext}}_x$ 3-D+ is an even function of $x$. }

and y, while the anomaly of the y component of $\mathbf{H}^{(ext2)}$ 3-D− is an odd function of x and y plus a constant. For $\mathbf{H}^{(ext2)}$ 3-D+, similarly to the behaviour observed for $\mathbf{H}^{(ext1)}$ 2-D+ and 3-D+, $\rho_{xy}$ is depressed and $\phi_{xy}$ is enhanced below the centre of the anomaly of this field. In addition, $T_y$ is not null. The field $\mathbf{H}^{(ext2)}$ 3-D− produces narrow zones of extremely high resistivity and tipper.

We can conclude that at a period of 24 h, below the central part of the anomalies of all the $\mathbf{H}^{(ext1)}$ fields considered, the generalized TE responses are completely dominated by source effects and are very different from the MT TE mode response. Conversely, the source effects produced by the two fields $\mathbf{H}^{(ext2)}$ are more localized and relatively less important, such that a great part of the MT TM mode response can still be appreciated, even at this large period.

Although these results were obtained for a particular kind of 2-D structure, and for particular types of external fields, they provide some basic conclusions that could be extended to other analogous situations.
