Acta Crystallographica Section C: Crystal Structure Communications specializes in the rapid dissemination of high-quality studies of crystal and molecular structures of interest in fields such as chemistry, biochemistry, mineralogy, pharmacology, physics and materials science. The numerical and text descriptions of each structure are submitted to the journal electronically as a Crystallographic Information File (CIF) and are checked and typeset automatically prior to peer review. The journal is well known for its high standards of structural reliability and presentation. *Section C* publishes approximately 1000 structures per year; readers have access to an archive that includes high-quality structural data for over 10000 compounds.

Crystallography Journals Online is available from journals.iucr.org

Two isomorphous transition metal complexes displaying a coordinated tetrathionate unit: bis(4,4'-dimethyl-2,2'-bipyridine- κ^2N,N')(tetrathionato- κ^2S,S')cadmium(II) dimethylformamide disolvate and the zinc(II) analogue

The isomorphous title compounds, $[Tr(S_4O_6)(C_{12}H_{12}N_2)_2] \cdot 2C_3H_7NO$ ($Tr = Cd^{II}$ and Zn^{II}), consist of metal centres to which one tetrathionate and two 4,4'-dimethyl-2,2'-bipyridine chelating ligands bind. The structures are completed by two symmetry-related dimethylformamide solvent molecules. Each metal-centred complex is bisected by a twofold axis running through the metal centre and halving the chelating tetrathionate dianion through the central S–S bond. The ancillary symmetry-related 4,4'-dimethyl-2,2'-bipyridine ligands act as chelates. This results in a distorted six-coordinate geometry, with similar Tr –O/N distances but central angles differing substantially from 90 and 180°. Both ligands are basically featureless from a geometric point of view, with torsion angles in both coordinated tetrathionate groups suggesting a trend linking metal size (covalent radius) and ligand ‘openness’. Packing is directed by (C–H)_{aromatic}···O bridges and π – π offset stacked interactions defining chains along [001], further linked by weaker (C–H)_{methyl}···O bridges, some of them mediated by the dimethylformamide solvent molecules.

Comment

For an extended period of 40 years [*viz.* those between the reports of Baggio & Baggio (1973) and Suarez *et al.* (2013)], our group has been interested in the coordination affinity towards transition metals of a variety of different sulfur oxo-anions (sulfate, sulfite, thiosulfate, peroxodisulfate, di/tri/tetra-

pentathionate *etc.*) in organic–inorganic coordination compounds. Even though many of them show a remarkable coordination tendency (SO_4^{2-} , SSO_3^{2-} *etc.*), others, in particular the latter ‘thionate’ family, present extremely poor binding abilities. This is readily confirmed by a search of the Cambridge Structural Database (CSD, Version 5.33; Allen, 2002), comparing for each ligand the total number of entries (m) with the number of entries involving the coordinated ligand (n), represented as (m,n) : dithionate (125,13), trithionate (4,1), tetrathionate (19,2) and pentathionate (8,0). The case of tetrathionate is particularly interesting; only two out of 19 structures in the CSD show the anion acting in a coordinating mode [Freire *et al.* (1998) showed it bridging Cu atoms and Freire *et al.* (2001) showed it chelating an Mn atom], and in both cases the ligand had been generated serendipitously during the synthesis procedure as an oxidation product of $S_2O_3^{2-}$, which thus acted unexpectedly as a precursor. In summary, no direct synthesis starting from any $S_4O_6^{2-}$ derivative has so far resulted in any transition metal complex with a coordinated tetrathionate group. In order to explore this puzzling situation further, we tried to ‘fine tune’ the synthesis and crystallization of different $S_4O_6^{2-}$ transition metal compounds (see *Experimental* section for details). We present herein the first two successful results of these attempts, the isomorphous Cd and Zn title complexes, namely bis(4,4'-dimethyl-2,2'-bipyridine- κ^2N,N')(tetrathionato- κ^2S,S')cadmium(II) dimethylformamide disolvate, $[Cd(tth)(dmbpy)_2] \cdot 2DMF$, (I) (Fig. 1a), and the zinc(II) analogue, $[Zn(tth)(dmbpy)_2(tth)] \cdot 2DMF$, (II) (Fig. 1b), where dmbpy is 4,4'-dimethyl-2,2'-bipyridine, tth is the tetrathionate anion and DMF is dimethylformamide.

The molecules of both isomorphs consist of a *d*-block metal (Tr) cation [$Tr = Cd^{II}$ for (I) and $Tr = Zn^{II}$ for (II)], to which one tth and two dmbpy chelating ligands bind. The structures are completed by two symmetry-related DMF solvent molecules. Each complex molecule is bisected by a twofold axis running through the metal centre and halving the chelating tth anion through the central S–S bond. The ancillary symmetry-related dmbpy ligands also act as chelates. The metal cations present a 2+2+2 N₄O₂ environment. As expected, this results in a distorted six-coordinate geometry, with similar Tr –O/N distances (Tables 1 and 2), but with the central angles differing substantially from 90 and 180° [90±18.78 (6) and

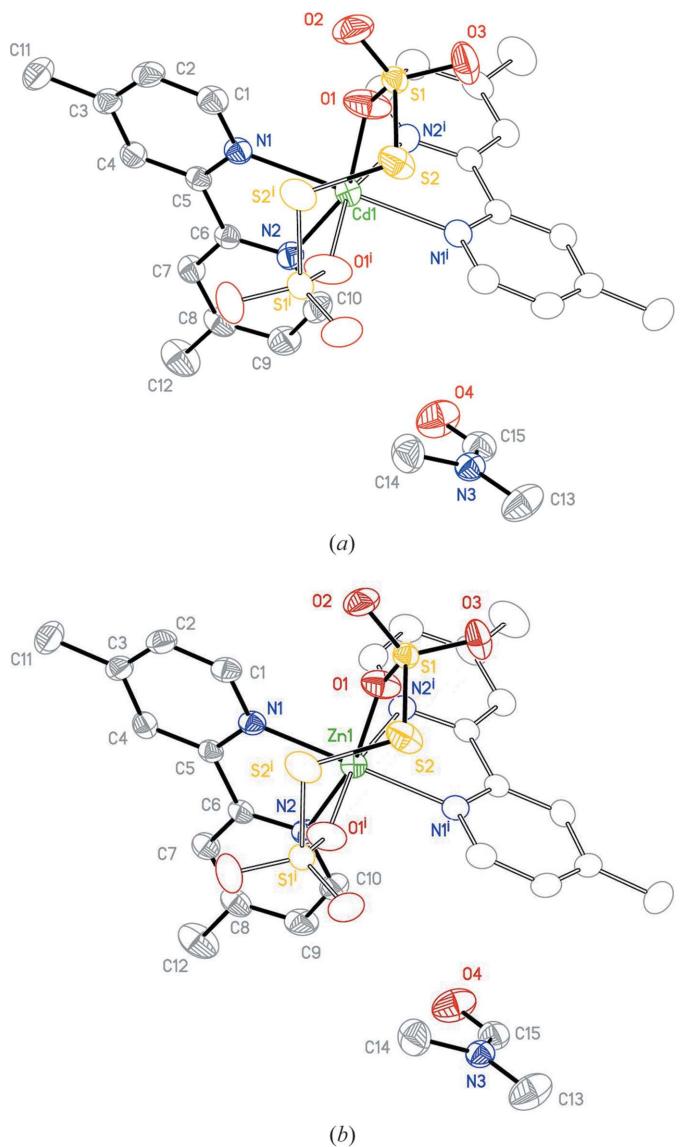

Figure 1

Molecular views of (a) (I) and (b) (II), showing the atom-numbering schemes. Displacement ellipsoids are drawn at the 30% probability level. Shaded ellipsoids and solid bonds represent the independent part of the molecule. [Symmetry code: (i) $-x + 1, y, -z + \frac{1}{2}$]

180 ± 22.44 (7) $^\circ$ for (I), and 90 ± 12.80 (10) and 180 ± 13.27 (9) $^\circ$ for (II).

The dmbpy units are planar, with maximum deviations of -0.033 (2) and 0.032 (2) Å for (I), and -0.030 (2) and 0.018 (2) Å for (II), corresponding in both cases to the terminal methyl groups.

The tth ligands chelate the metals in a similar manner to that found in the Mn-bipyridine analogue (Freire *et al.*, 2001). They present standard metric features, with clearly differentiated outer and central S–S bond lengths [2.1011 (10) *versus* 2.0169 (15) Å for (I) and 2.1056 (13) *versus* 2.016 (2) Å for (II)], as well as S=O and S–O bond lengths [1.403 (2)–1.4165 (18) *versus* 1.4297 (19) Å in (I) and 1.417 (2)–1.424 (2) *versus* 1.442 (2) Å in (II)], and they seem to adjust their flexible spatial conformation to the different metal sizes; the

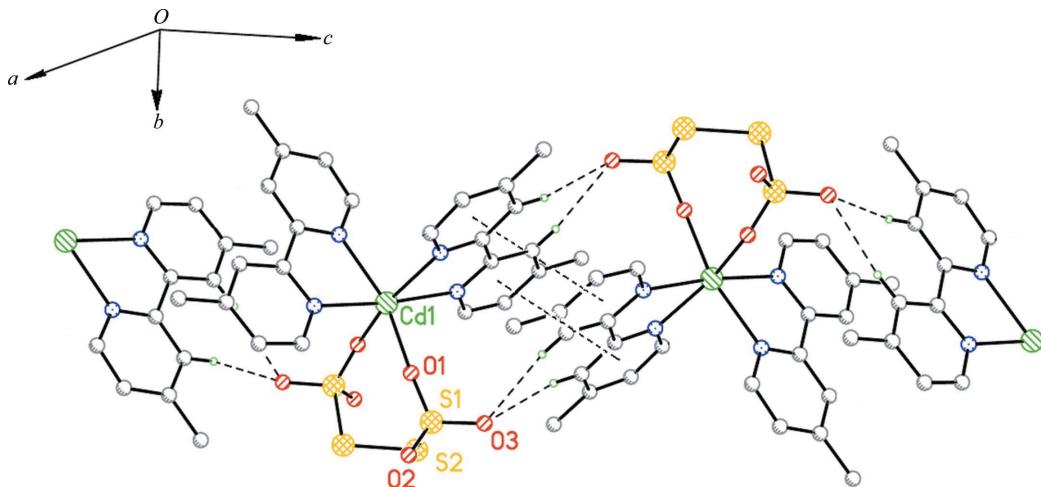

O1–S1–S2–S2ⁱ and S1–S2–S2ⁱ–S1ⁱ torsion angles [symmetry code: (i) $-x + 1, y, -z + \frac{1}{2}$] along the anion ‘backbone’ are -55.99 (11) and 105.22 (5) $^\circ$ for (I), and -59.05 (12) and 99.48 (6) $^\circ$ for (II), respectively. Given that in an A–B–C–D torsion angle a 90° value corresponds to perpendicular ABC/BCD planes and a 0 or 180° value to parallel planes, a smaller or larger departure from 90° can be indicative of a more ‘closed/open’ character of the tth anionic group. It transpires (perhaps expectedly) that this case appears more ‘open’, with large departures from 90° . Similar results are obtained by comparing the S1···S1ⁱ distances in the coordinated anions, *viz.* 4.428 (2) Å for (I) and 4.331 (2) Å for (II).

As stated above, the donor atoms in (I) and (II) cannot fit in any regular polyhedron, but the three chelate ligands abide by the vector bond-valence postulate of the vectorial bond-valence model [for details on the theory, see Harvey *et al.* (2006)]. The three ligand vectors, as defined therein, lie in a planar trigonal geometry, with the sum of the angles being 360.0 (2) $^\circ$ for both (I) and (II) (ideal = 360°), and with resultant vector moduli of 0.085 valence units (v.u.) for (I) and 0.049 v.u. for (II) (ideal = 0.00 v.u.). The usual bond-valence sums (BVS; Brown, 2002) are 2.00 v.u. for Zn and 2.17 v.u. for Cd¹.

In spite of the lack of good hydrogen-bond donors, which weakens the interactions between monomers, packing indices [as calculated by PLATON (Spek, 2009), following Kitajgorodskij (1973)] are very near the expected average of *ca* 65% [66.15% for (I) and 67.4% for (II)].

Tables 3 and 4 present relevant C–H···O hydrogen bonds, while Table 5 gives information on the π – π interactions. The first three entries in Tables 3 and 4 correspond to the more active (C–H)_{aromatic} group, and in fact these have a definite structural role. Fig. 2 shows the way in which the interactions presented as the first two entries serve to link adjacent molecules in a self-complementary fashion along the [001] direction, in the form of well defined chains, complemented by the π – π interactions between offset stacked dmbpy groups. The third entry in Tables 3 and 4 binds the DMF solvent molecules to the main molecule. The remaining three entries involve the less active (C–H)_{methyl} groups, and these interactions ultimately have the role of interlinking chains together in a rather weak fashion.

¹ In our experience with Cd complexes, we have detected that the bond-valence parameters presented by Brown (2006) for Cd–O and Cd–N ($R_{\text{Cd}–\text{O}} = 1.904$ and $R_{\text{Cd}–\text{N}} = 1.960$) usually lead to overestimated BVS values for the cation. This is not unexpected, since it is known that these parameters are not absolutely ‘universal’ but depend on, among other features, the coordination environment (Brown, 2008). We attempted to find better values for both bond-valence parameters and so, while keeping ‘ b ’ fixed at its standard value of 0.37, we performed a least-squares fit on *ca* 2000 CdO_nN_{6–n} coordination polyhedra in the CSD (Allen, 2002) of the valence sum equation $\sum(V_i)_{i=1-6} = V$ [with $V = 2$ the expected Cd valence and $V_i = \exp(R_x - R_i)/b$], where $R_x = R_{\text{Cd}–\text{O}}$ or $R_{\text{Cd}–\text{N}}$ are the parameters to be refined, and R_i are the actual Cd–O and Cd–N bond lengths. Upon convergence, this procedure led to slightly different values than those given by Brown (2006) (about 1% smaller, *viz.* $R_{\text{Cd}–\text{O}} = 1.886$ and $R_{\text{Cd}–\text{N}} = 1.946$) and with better performance; they resulted in a BVS for Cd1 in (I) of 2.17 *versus* a value of 2.26 calculated from Brown’s data.

**Figure 2**

A simplified view of the [001] chain in (I). C—H···O hydrogen bonds and π — π interactions are shown as dashed lines.

This differentiated interaction scheme serves to provide, if not an explanation, at least a plausible argument for the behaviour of the cell metrics, *viz.* the increase in the *c* cell dimension when going from Zn to Cd (an expected fact), but a small decrease in the remaining two cell dimensions, more pronounced in the *a* dimension. Fig. 2 helps in understanding the increase along the [001] chains; this is the overall direction of the Cd—N bonds ($\sim 10\%$ longer than the corresponding Zn—N bonds), as well as of the bridging (C—H)_{aromatic}···O hydrogen bonds and π — π interactions, thus rendering the *c* cell dimension longer (and more rigid).

Along the remaining two directions, chains are instead held together by much more labile forces [mainly (C—H)_{methyl}···O contacts; Fig. 3]. These are, accordingly, ‘soft’ directions which

would not provide strong resistance to any eventual compression required by the close packing of the chains.

Experimental

In several previous attempts to obtain hybrid organic tetrathionate transition metal complexes using aqueous solutions, the anion decomposed systematically, yielding thiosulfate. In view of these failures, we thought of using a solvent in which the organic ligand is soluble but the other two components are only slightly soluble. In doing so, it was expected that the components would mix slowly to form the complex, while simultaneously displacing the solubility equilibrium. After some tests, we selected dimethylformamide (DMF) as an appropriate solvent. To a solution of 4,4'-dimethyl-2,2'-bipyridine in DMF (5 ml, 0.050 *M*), solid Cd or Zn diacetate dihydrate and potassium tetrathionate were added in a mass–volume ratio chosen to give a 0.050 *M* solution of each component. On standing, in both cases, a poorly crystallized precipitate appeared, which was digested over a period of time (one week in the Cd case and one month for Zn) to give crystals of the expected complexes in the form of well faceted colourless blocks suitable for X-ray diffraction analysis.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
