Dear Editor,

Please, find attached the manuscript entitled:

An approach to Agent-Based modeling with Modelica

by: Victorino Sanz, Federico Bergero and Alfonso Urquia

We have revised it following the received comments and we'd like it to be considered for publication in *Simulation Modelling Practice and Theory - Special Issue on Agent-Based Modelling and Simulation*.

The author to whom correspondence should be addressed is the following:

Victorino Sanz
Dept. Informatica y Automatica
E.T.S. de Ingenieria Informatica, UNED
Juan del Rosal 16, 28040 Madrid, Spain
E-mail: vsanz@dia.uned.es
Tel. +34 913989469

Best regards,
The manuscript authors.

RESPONSE TO REVIEWER 2

Reviewer comment:

Having Fig 3 and 4 on one page would improve readability.

Author's response:

Figures 3 and 4 have been situated in the same page as suggested.

Reviewer comment:

Reference 3 doesn't fit the page. Depending on the citation standard it might also be desirable to state the date of websites as "visited: 2017-09-12" or something similar.

Author's response:

The following note has been included in reference 3: [online; accessed 14-Dec-2017].

Reviewer comment:

Reference 14 has 3 links to doi.org - at least the URL part at the end could be removed. Also it seems to be the only reference including a doi. A complete removal of all doi links would probably fit best.

Author's response:

The URL and DOI parts of reference 14 have been removed as suggested.

Reviewer comment:

Reference 16 can't be used like this. I admit that it is hard to find a good way of referencing this standard but I definitely don't like the presented form. Adding a link to the standard document would at least improve it.

Author's response:

Reference 16 has been completed with the URL link to the mentioned document, including the note with the date of access as suggested with reference 3.

An approach to Agent-Based modeling with Modelica

Abstract

Modelica is a free, general-purpose object-oriented equation-based modeling language. It is mainly designed to describe systems using the physical modeling approach. Our proposal to describe Agent-Based Models (ABMs) in Modelica is discussed in this manuscript. The contribution of the presented work is twofold: firstly, to analyze the conceptual requirements to describe ABMs in Modelica; and secondly, to develop a prototype implementation following the previous analysis. Agents are described using a message passing communication mechanism previously proposed by the authors. Additional extensions to this mechanism are proposed in order to describe agent interactions. The environment, where the agents live, is described as a two-dimensional cellular automaton. A new Modelica library, named ABMLib, developed to support this functionality, is presented. A prototype implementation of the message passing mechanism and ABMLib models has been performed to demonstrate the functionality of the library as a proof-of-concept for this proposal. The library is freely available at www.euclides.dia.uned.es/vsanz.

Keywords: Agent-based model, Modelica, hybrid systems

9 **1. Introduction**

10
11 Agent-Based Models (ABMs) are discrete-event models composed of a vari-
12 able number of “living” objects, named agents, that behave following a pre-
13 defined set of rules (i.e., agent behavior), and interact among them and with
14 their environment (i.e., the physical space where the agents “live”) [1]. The in-
15 5 individual behavior of each agent is defined using simple rules, or algorithms, but
16 the simulation of the whole model may lead to complex and emergent behav-
17 iors. In this manuscript, the description of ABMs using the Modelica language
18 is discussed.
19
20
21
22
23

24
25 10 Modelica supports the description of mathematical models following the
26 physical modeling paradigm [2]. Modelica models are described as a combi-
27 nation of acausal equations, algorithms and events, using the hybrid DAE for-
28 malism (cf. [3] for a detailed description of the formalism). The causality of the
29 model is automatically computed by means of symbolic manipulations of the
30 equations before generating the executable code [4].
31
32 15

33
34 The description of ABMs in Modelica could be used to perform a qualitative
35 description of models, or parts of models, in contrast with the quantitative ap-
36 proach given by equation-based modeling [5]. ABMs can be used to represent
37 heterogeneous objects in the model (i.e., agents of the same type are used to
38 represent different individuals in the model with different characteristics or even
39 different behavior) while equations are used to represent homogeneous quanti-
40 20 ties. Adaptive or learning behaviors can also be described in terms of ABMs.
41 In this way, the combination of ABMs with other Modelica models enhances
42 the functionality of the language and the description of more complex hybrid
43 systems.
44
45
46
47
48 25

49
50 Other authors have made efforts to combine equation-based models and
51 ABMs. The LEADSTO language combines dynamic systems of equations with
52 ABMs [6]. Another approach has been to combine ABMs with System Dynam-
53 ics, using Anylogic, to describe health-care systems [7]. Humans are described
54 using agents, while System Dynamics is used to describe disease dynamics. A
55
56 30

1
2
3
4
5
6
7
8
9 similar approach is used to simulate antibiotic resistance in hospital wards [8].
10 Intra-host dynamics (i.e., bacterial-level processes inside individuals) are de-
11 scribed using differential equations, while inter-host dynamics (i.e., relations
12 between humans) are described using ABMs. Also, Dymola and JADE have
13
14
15
16 35 been combined using a co-simulation approach to describe control for office
17 spaces [9].

18
19 The proposal presented in this manuscript is to describe agents as individual
20 messages flowing between components of a flowchart diagram, which is analo-
21 gous to a coupled DEVS model [10]. Agent behavior is described by the compo-
22
23
24 40 nents of the flowchart diagram independently of the environment, but agents can
25 interact with it. The environment is represented as a two-dimensional cellular
26 automaton, using CellularAutomataLib2 [11]. Some extensions to the message
27 passing communication mechanism, previously proposed by the authors [12], are
28 presented to describe agent's interactions. All this functionality is included in a
29
30
31 45 new Modelica library, named ABMLib, designed and developed by the authors.
32 ABMLib models can be also combined with other Modelica models. ABMLib
33 approach is similar to the description of systems using process calculus, where
34 the processes communicate using messages [13]. However, in this proposal agent
35 actions are not synchronized by means of communication rendezvous, but at
36
37
38
39 50 discrete points in time [14]. ABMLib approach is also similar to actor-oriented
40 models, but in this case messages represent the agents themselves and not the
41 data flowing between actors.
42
43

44 A prototype implementation of the message passing mechanism and the
45 new library has been developed and tested, and an application example using
46
47 55 a Lotka-Volterra model is presented in this manuscript. The presented model
48 combines ABMs with continuous-time equations in order to illustrate the ben-
49 efits of supporting ABMs in Modelica.
50

51 The structure of the manuscript is as follows. The requirements to describe
52 ABMs in Modelica are discussed in Section 2. The message passing communi-
53
54
55 60 cation mechanism is briefly described in Section 3, together with the proposed
56 extensions required for ABM development. The ABMLib library is described in
57
58

1
2
3
4
5
6
7
8
9 Section 4, and the combination of ABMLib models with other Modelica models
10 is described in Section 5. The Lotka-Volterra model described using ABM-
11 Lib and other Modelica functionality is presented in Section 6. Finally, some
12 conclusions and future work ideas are given in Section 7.
13
14 65

15 16 17 **2. Requirements for describing ABMs in Modelica** 18

19 Modelica and ABM are conceptually different. ABMs are composed of
20 agents, environments and interactions [1]. Modelica models are mainly de-
21 scribed by means of equations, while the behavior of agents is described us-
22 ing rules. Agents can be created or removed during the simulation run, while
23
24 70 ing rules. Agents can be created or removed during the simulation run, while
25 the number of variables and equations in Modelica has to remain constant.
26 ABMs are usually dependent on the spatial coordinates, with the agents mov-
27 ing and interacting around the environment, while the only independent variable
28 in Modelica is the time. The functionality of the Modelica language that can
29
30 be used to describe these characteristics is discussed below.
31
32 75

- 33
34 • Agents are described by means of their state and behavior. Modelica
35 simple data types and complex data structures can be used to represent
36 the state of the agents. Usually, the behavior of agents is described as a
37 set of rules or actions. Modelica algorithm sections can be used to describe
38 the behavior of the agents.
39
40 80

41
42 However, Modelica does not support changes in the number of variables
43 and/or equations during the simulation. These changes occur during the
44 creation or removal of agents from the model. An additional mechanism
45 needs to be used to represent the variation of agents during the simulation.
46
47

48
49 85 The proposed approach is to graphically represent the behavior of agents
50 as a flowchart diagram. Agents are represented as messages that are sent
51 from one component to another in the diagram. The components repre-
52 sent the individual actions performed by agents. The diagram includes
53 components to create agents and to remove them from the simulation.

90 The components of the diagram communicate using the message pass-
ing communication mechanism previously proposed by the authors [12],
which is capable of dealing with a variable number of messages during the
simulation run.

- The environment represents the physical space where the agents behave
95 and interact, and can be defined in multiple ways depending on the ne-
cessities of the model. Some authors consider the environment as a set of
passive agents, since they can also have state and behavior [15]. Also, the
environment could only represent feasible agent interactions (e.g., links in
a social network).

100 As a first approach, our proposal is to represent the environment as a
cellular automaton. This is a two-dimensional square lattice, where the
states of the cells are represented using some variables and all the cells
share the same behavior defined using a transition function. The state
of the cells is periodically updated using the transition function. The
105 CellularAutomataLib2 library, developed by the authors, supports the de-
scription and efficient simulation of cellular automata in Modelica [11].

- Agents can interact with other agents or with the environment. Model-
ica provides functionality to access models and variables in the hierarchy
of models and libraries of models. This functionality includes the dot-
110 notation, that allows to access models in other libraries or packages, or
the `inner/outer` variable modifiers that can be used to access variables
and models defined in another part of the hierarchy. Additionally, Cellu-
larAutomataLib2 includes interface models to combine cellular automata
with other Modelica models. These interface models, combined with the
115 other Modelica functionality, can be used to observe or modify the state
of the environment depending on the behavior of the agents.

On the other hand, since each agent is defined as a message and they
move between the components of the flowchart diagram, the state of the
agents is not accessible. Additional functionality is required to describe

120 agent interactions. An extension to the message passing communication
mechanism, with the concepts of sets and subsets of messages, is proposed.
This new extension is detailed next.

3. Message Passing Communication Mechanism

Coupling relationships between Modelica components are described using:
125 the `connector` class to define the ports of their interfaces, and the `connect` sen-
tence to define the connection between connectors. Each connector is composed
of a set of variables that by default are defined as *effort*, and may be defined as
flow using the `flow` modifier. The *effort* variables of the connected connectors
are equaled, and the *flow* variables are summed up and the sum is equaled to
130 zero. These connect-equations are added to the model and taken into account
with the rest of the model in order to perform the causality analysis.

Message passing corresponds to the transference of one or multiple impulses
of information between models, in contrast with the equation-based connec-
tions previously described. Both communication approaches are conceptually
135 different, and thus the authors proposed to include new functionality in Mod-
elica in order to support message passing communication. A new class, named
`buffer`, and a new sentence, named `couple`, are introduced to describe commu-
nication buffers and their relationships. The proposed extensions are based on
the P-DEVS model communication approach [10]. These extensions are briefly
140 introduced in Section 3.1, and a detailed description can be found in [12].

Message passing communication can serve as a general purpose extension to
Modelica, since it can be applied to describe systems using multiple approaches,
such as DEVS, process-oriented models and distributed models, among others.
Message passing libraries already exist for general purpose programming lan-
50 guages, like the Message Passing Interface (MPI) [16]. In this manuscript the
145 use of message passing communication is focused on the description of ABMs.
However, the mechanism proposed in [12] needs to be extended to describe
the interactions between agents. These additional extensions are presented in

1
2
3
4
5
6
7
8
9 Section 3.2.

10
11
12 150 *3.1. Previous Proposal*

13 The elements of the communication mechanism are the messages, the buffers
14 and the communication channel. A brief description of the proposed message
15 passing communication mechanism is presented.
16
17

- 18
19 • *Messages* represent the information transported from one model to an-
20 other. They can be defined using current Modelica functionality, such as
21 155 basic data types (e.g., `Integer`, `Real` or `Boolean`) or more complex data
22 structures using `record` classes.
23
24
- 25
26 • *Buffers* constitute the data structures used to store messages. They can
27 be used to store a variable number of messages in a model, or as interface
28 ports for communicating with other models using the `input` and `output`
29 Modelica modifiers. The messages in a buffer can be read using array-like
30 160 and dot-notation (e.g., `buffer[1]` for accessing the first message in the
31 buffer, or `buffer[1].var` for accessing a variable in the first message).
32 Two special functions, named `put` and `pop`, can be used to insert and
33 extract messages to and from the buffer respectively. The number of
34 165 messages in a buffer is automatically computed and stored in a variable
35 named `size` (e.g., `buffer.size`).
36
37
- 38
39 • The *Channel* is used to define the communication relationships between
40 models. Similarly to the `connect` sentence, a new sentence, named `couple`,
41 170 is introduced to define relationships between input and output buffers.
42 Point to point and collective (i.e., 1-N, N-1 and N-N) communication are
43 allowed.
44
45
46
47
48
49

50
51 As described above, messages can be used to represent agents. The actions
52 required to describe the behavior of agents can be defined as the actions as-
53 sociated with the management of input messages in a model. This modeling
54 175 approach can be described in terms of the P-DEVS formalism and is similar
55
56
57
58

1
2
3
4
5
6
7
8
9 to the implementation of SIMANLib and ARENALib, which are two Modelica
10 libraries developed by the authors that support the process-oriented modeling
11 worldview [17].
12

13
14 180 The behavior of each agent type is defined using a flowchart diagram. All
15 the agents of a particular type will be stored in the buffers of the components of
16 their diagram. An additional extension to this message passing communication
17 mechanism is presented next to allow agent interactions.
18
19
20

21 *3.2. Additional Language Extensions*

22

23 185 In order to allow the interaction between agents, two additional data struc-
24 tures are proposed as new Modelica classes: `msgset` and `msgsubset`. These
25 new classes constitute language extensions, since their functionality cannot be
26 described using Modelica.
27
28

29 The `msgset` class represents the set of messages that are stored in the buffers
30 of a model and its components, including interface ports and internal buffers.
31 190 The contents of the `msgset` object are automatically updated by the simulator,
32 adding or removing messages as required. In order to avoid duplicities between
33 `msgset` objects and the buffers of the model, the `msgset` object should only
34 store references to the actual messages. The `msgset` class can be used to access
35 the information carried by the messages using array-like and dot-notations (e.g.,
36 `set[1].a` defines the value of the variable `a` of the first message in the `set`).
37 Note that the index of the array is not representative since buffers and sets are
38 unordered data structures, so additional mechanisms have to be used to identify
39 195 individual messages (e.g., unique message identification numbers). The number
40 of messages in the set is automatically computed and stored in a pre-defined
41 `size` variable. In ABMs, a `msgset` object can be used to have access to all the
42 agents flowing in a flowchart diagram.
43
44
45
46
47 200
48
49
50

51 However, the interaction between agents is usually restricted to a particular
52 reduced set of agents. The `msgsubset` class represents a subset of messages
53 that share a given condition (e.g., agents located in the same position or in the
54 205 neighborhood). The subset has two parameters: the `sources` that are the set or
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4
5
6
7
8
9 sets from where the subset is composed of; and the `condition` that defines the
10 common characteristic for all the messages in the subset. The condition is used
11 to compare the values of the messages in the sources with other values. The ':'
12 Modelica operator could be used to index all the messages in the sources (e.g.,
13 `sources[:].X == x`, meaning that all the messages in the sources with a value
14 of `X` equal to `x` will belong to the subset). The authors propose to simplify the
15 notation and remove the reference to the array. In that case the same condition
16 will be written as `sources.X == x`.
17
18
19
20

21
22 An additional problem arises when the condition is based on the values of the
23 variables of a message that is currently being processed. For example, an agent
24 that needs to interact with other agents located in the same spatial position.
25 In this case the condition for the `msgsubset` could be written as `sources.X ==`
26 `agent.X and sources.Y == agent.Y`, where `X` and `Y` are the spatial coordi-
27 nates of the agents. That condition will be different for each agent, depending
28 on their spatial position, so a different subset has to be computed for each agent.
29 The introduction of a new Modelica operator, named `msg`, is proposed to facil-
30 itate the description of such conditions. The value of `msg` corresponds to the
31 value of the last message extracted from one buffer using the `pop` function (i.e.,
32 `msg` corresponds to the last active message in a model). Different models may
33 have different values for `msg`, since messages can be simultaneously received and
34 managed. Thus, the condition defined above could be written as `sources.X`
35 `== msg.X and sources.Y == msg.Y`. The `msg` operator can also be used to ac-
36 cess the variables of the active message, to define other conditions or parameter
37 values in the components of the flowchart diagram.

48 **4. The ABMLib Library**

49

50
51 ABMLib is a new Modelica library that facilitates the description of ABMs in
52 Modelica, and their combination with other Modelica models. The architecture
53 of the library is shown in Fig. 1. The library is composed of:
54
55

- 56 • `stdAgent` model that is used to describe a standard agent. It includes

some variables common to all agents.

- `obuffer` and `ibuffer` that represent the output and input buffers used to describe the interfaces of the components of the flowchart diagram.
- `Components` package that include some basic components that can be used to describe the behavior of agents.
- `stdCell` and `Environment` that can be used to represent a basic agent environment. As described above, the `CellularAutomataLib2` library provides better functionality to describe the environment and its use is encouraged.
- `Examples` package that includes some examples of use.

Figure 1: ABMLib library architecture.

Since ABMLib is based on the proposed message passing communication mechanism and that is not yet part of the Modelica specification, ABMLib models cannot be simulated with standard Modelica tools. The implementation proposed by the authors is described in Section 6. Briefly, the support for flattening ABMLib models has been included in the ModelicaCC compiler

1
2
3
4
5
6
7
8
9 [18]. This implementation includes support for describing buffers and couple
10 sentences. The process generates Modelica flat code that can be simulated us-
11 ing a standard Modelica tool (OpenModelica in our case). The generated code
12 includes calls to external functions in C that contain the actual implementation
13
14
15
255 of the message passing communication. Some manual modifications have to be
16 performed to the model in order to correctly generate the flat code. As a result,
17 ABMLib should be considered as a proof-of-concept library for supporting ABM
18 in Modelica.
19
20

21 An ABM described using ABMLib is composed of *agent types*, at least one,
22
23
260 that defines the characteristics and behavior of a kind of agent that populates
24 the model (i.e., cars, humans, sheep, wolves, ants, etc.), and one *environment*
25 model that describes the characteristics and behavior of the world where agents
26 live. Agent types may include functionality to define their behavior and the
27 interaction between different agent types (e.g., humans and cars). All these
28 components are detailed next.
29
30
31
265

32 33 34 *4.1. Agent Type*

35 An agent type is a Modelica model that includes the characteristics of the
36 agent and its behavior.
37

38 The record that describes the agent characteristics is used as data structure
39
40
270 to create the messages that represent the agents flowing in the diagram. ABM-
41 Lib includes a partial record, named `stdAgent`, that contains some common
42 variables for all agent types: position in the environment, orientation, color,
43 identification number, agent type name and the buffer where the agent is lo-
44 cated before being moved to another destination. The `stdAgent` record can
45
46
47
275 be extended, and thus its variables inherited, by other records to facilitate the
48 description of the characteristics of other agents. The Modelica code for the
49 `stdAgent` record and the declaration of a new agent, named `car`, is shown in
50 Listing 1.

Listing 1: ABMLib agent partial record code.

```
partial record stdAgent
  Integer X; // X coordinate
  Integer Y; // Y coordinate
  Integer head; // head orientation in degrees
  Real color; // color for graphical animation
  Integer ID; // identification number
  String name; // agent type name
  buffer origin; // buffer of origin before send
end stdAgent;

record car extends stdAgent(name="car");
  Real kms; // kilometer count
  Real fuel; // amount of fuel
  Integer passengers; // number of passengers
end car;
```

4.2. Agent Behavior

280 The behavior of an agent type is described by means of a flowchart diagram. Agents are created in the diagram and flow through its components following the structure of its links and performing the actions defined by the components. All the inter-connected components of a flowchart diagram have to manage the same agent type, which is specified as a parameter of each component additionally to other parameters. In order to describe the flowchart diagram, ABMLib includes 285 the components listed below. A graphical description of their interfaces is shown in Fig 2. Ports with two stripes represent buffers for message communication and the rest are Boolean inputs and Real outputs.

- 290 • *Create*, represents the starting point for the agents in the diagram. Agents are created in batches of a given size.
- *Dispose*, represents the ending point for the agents. Agents that arrive to this component are removed from the model.
- *Assign*, represents an assignment to a variable of the agent or the model,

in response to the arrival of an agent.

- 295 • *Decide*, represents a bifurcation in the flow of agents based on the value of a boolean condition. If multiple conditions need to be meet, multiple *Decide* components should be consecutively nested.
- *Count*, represents a point where basic statistical information of the model is computed based in the flow of agents.
- 300 • *Duplicate*, represents the creation of a duplicate of an agent. The duplicate agent is an exact copy of the original agent, but it has a different identification number.
- *Tick*, represents the point where the agents wait for a time unit to be elapsed (i.e., a tick of time).

305 Note that some variables have been included in the components to facilitate the analysis of the simulations (e.g., number of disposed agents, number of agents in each decision branch, counters, etc.). This information can be used to observe the evolution of the model and perform a basic analysis of the simulation results. More detailed and complex information, such as statistical indicators,

1
2
3
4
5
6
7
8
9 310 can be included in these or other custom made components to perform more
10 complex analyses.
11

12 4.3. Agent Interaction

13
14
15 Agent interaction happens when the actions performed by an agent depend
16 on the state of other agents, or when they directly modify the state of other
17 agents. 315 These two kind of interactions can be described using the proposed
18 extensions to the message passing communication mechanism: the `msgset` and
19 `msgsubset` classes.
20
21

22
23 The `msgset` and `msgsubset` objects can be used to access the state of other
24 agents, like any other model variable. The values of the state variables of other
25 agents can be used to configure the parameters or conditions in the flowchart
26 320 diagram of an agent type.
27
28

29
30 On the other hand, an additional flowchart component has to be included
31 in order to influence the state of other agents. The *Send* component has been
32 included in ABMLib for this purpose. This component can be used to extract
33 an agent from its current buffer and send it to a new destination (i.e., another
34 325 flowchart diagram) that represents the new actions to be performed by that
35 agent. For example, when an agent *policeman* finds an agent *criminal* (e.g.,
36 both agents are located in the same coordinates in the environment) a *Send*
37 component can be used to send the criminal to another flowchart diagram that
38 represents the stay in jail. The parameters of the *Send* component are the agent
39 to be sent.
40
41 330
42
43
44

45 Note that since the agent sent to the destination is extracted from its
46 flowchart diagram, it will no longer be able to return to its normal behavior. In
47 order to facilitate the return of the agent to the point in the original flowchart
48 diagram before the movement, a variable named `origin` is included by default
49 335
50 in the state of the agent. This variable stores a reference to the original buffer,
51 and can be used with another *Send* component to return the agent back to its
52 behavior.
53
54
55
56
57
58

4.4. Environment

The environment represents the space where the agents move and behave. It can be described in multiple ways, but in order to simplify this proposal it is described as a uniform two-dimensional grid of square cells, as a cellular automaton.

Cells are described using a set of state variables and a transition function, which is periodically evaluated to update the state of the cells. The authors have developed the CellularAutomataLib2 library, which facilitates the description and efficient simulation of cellular automata in Modelica [11].

The interaction between agents and their environment can be described using the interface models included in CellularAutomataLib2. The *ExtInputRegion* model can be used to modify the state of the cells of the environment. The *OutputRegion* model can be used to observe the state of the cells of the environment, and use it to configure the behavior of the agents.

CellularAutomataLib2 models automatically generate a graphical animation of the simulation. This animation can also serve to analyze the simulation results of the ABMs.

5. Interface with other Modelica Models

Multiple free and commercial Modelica libraries that support modeling in multiple domains and with multiple formalisms are already available. The combination of these models with ABMLib models offers an extended functionality to describe more complex models. This combination is performed by including Modelica connectors in the ABMLib components. The values of the variables of these connectors can be observed and used to define the behavior of the agents, or vice-versa, the behavior of the agents can define the values of those variables in the connectors.

The following ABMLib components include connectors to interface with other Modelica models:

- Create, includes a Boolean input connector, named EXTIN, that can be used to control the creation of new agents using an external input. Every time the EXTIN port switches its value a new batch of agents is created.
- 370 • Assign and Count, both components include an EXTOUT connector of Real type that is assigned with the value assigned to the variable in the Assign component or with the new value of the counter in the Count component. Thus, the EXTOUT connector resembles a discrete-time piecewise constant signal.
- 375 • Decide, includes a Boolean connector, named COND, that can be used to define the condition used to divide the flow of agents.

6. Application Example: Hybrid Sheep-Wolves Model

In order to demonstrate the modeling functionality of ABMLib, an application example is presented. It corresponds to a Lotka-Volterra model where sheep and wolves coexist in the same environment (cf. [15], where it is implemented 380 and wolves coexist in the same environment (cf. [15], where it is implemented using Netlogo). The comparison between the Netlogo and ABMLib models helps to validate the simulation results and evaluate the modeling functionality of the latter.

Since one of the main advantages of describing ABMs in Modelica is the 385 possibility to combine equation-based models with ABMs, the presented model is described using a combined approach. Sheep are described as agents, while the wolves are described using the Lotka-Volterra equations for predator-prey models. Both parts of the model are described next.

6.1. Wolves

390 The Lotka-Volterra equations for predator-prey models are:

$$\dot{x} = \alpha x - \beta xy \tag{1}$$

$$\dot{y} = \delta xy - \gamma y \tag{2}$$

1
2
3
4
5
6
7
8
9 where, x represents the number of preys, y represents the number of predators,
10 and α , β , δ and γ are the parameters that describe the interactions between
11 both species.
12

13 The behavior of wolves, Eq.(2), can be directly coded in Modelica as:

14
15 `der(wolves) = C * sheep * wolves - D * wolves;`
16
17

18 Note that the number of sheep, `sheep`, is an input to this model and needs to
19 be computed by the agent-based Sheep model.
20

21 *6.2. Sheep*

22 Sheep agents are described using a Modelica record, named `SheepAgent`,
23
24 which is composed of three variables to represent the current energy of the
25 sheep, the energy gained from eating grass and the cost of moving.
26

27 The behavior of the sheep is as follows (the corresponding flowchart diagram
28 is shown in Fig.3). Sheep are created and a random position for each sheep is
29 assigned. After that, sheep behave in cycles defined using a tick component.
30
31 During each tick, each living sheep performs the following actions: they wiggle
32 and move around the environment searching for grass, while consuming energy.
33
34 Sheep die and are removed from the model when they spent all their energy.
35
36 Otherwise, they eat grass to gain energy and reproduce, which also consumes
37 energy. A counter is used to count the number of living sheep in the model,
38
39 which is the input required by the wolves model.
40

41 Before starting a new cycle, sheep can be hunt by wolves. Since wolves are
42 not described as agents, sheep are hunted using a probabilistic approach based
43 on the number of wolves computed by the equations (i.e., `wolves` variable in
44 the Wolves model).
45
46

47 Note that the Wiggle, Move, SheepEat, Reproduce and Hunted are coupled
48 components of the flowchart diagram. Their internal contents are graphically
49 shown in Fig. 4.
50
51

52 *6.3. Simulation*

53 An implementation of the message passing communication mechanism has
54
55 been included in the ModelicaCC compiler in order to simulate the model. Some
56
57

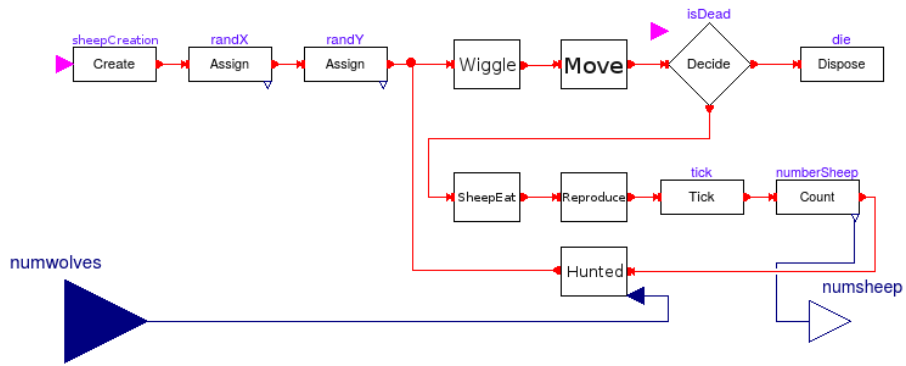

Figure 3: Flowchart diagram of the Sheep model.

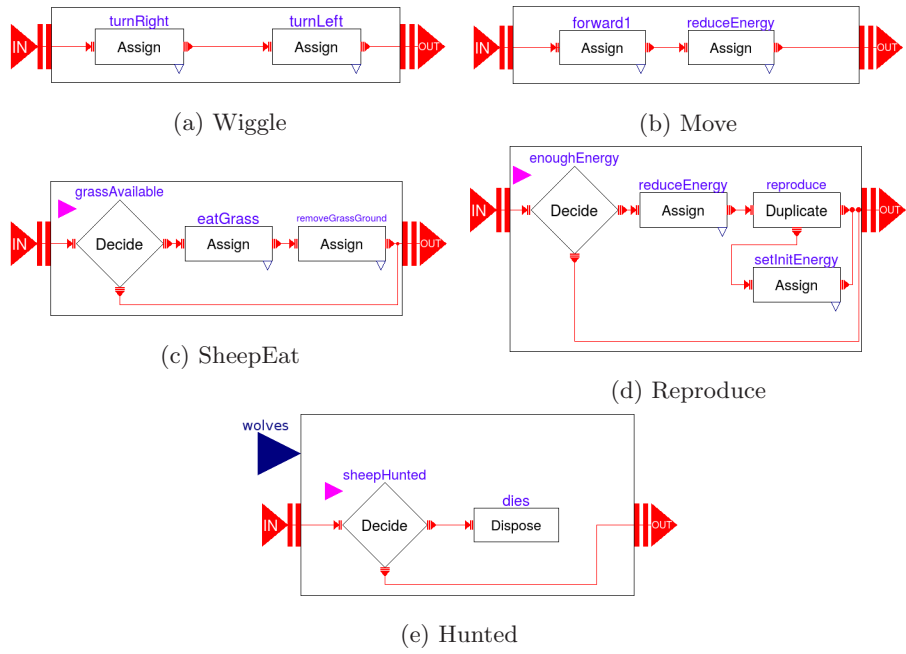

Figure 4: Sheep model coupled components.

1
2
3
4
5
6
7
8
9 additional features are required to flatten the ABMLib model and generate
10 standard Modelica code, that is simulated using OpenModelica.
11

12 The procedure to flatten and simulate the Hybrid Sheep-Wolves model is as
13 follows:
14

- 15 425 • A new class is included in the model to represent the buffers (i.e., `class`
16 `buffer`). Input and output buffers inherit this new class. While the
17 model is analyzed, the different types of buffers that appear in the model
18 are registered.
19
20
21
- 22 • Expressions using the `size` variable of a buffer are replaced with a call to
23 an external C function (e.g., `IN.size`, where `IN` is a buffer of type `B` is
24 430 replaced by a call to the C function `B_size(IN)`).
25
26
- 27 • A read access to the first element of a buffer is replaced by a call to the
28 external C function `peek` (e.g., `IN[1]` is replaced with `B_peek(IN)`).
29
30
- 31 • A read access to a variable in the first element of a buffer is similarly
32 replaced by a function (e.g., `IN[1].a` is replaced with `B_peek_a(IN)`).
33 435
34
- 35 • Two functions, named `B_put` and `B_pop`, are defined to substitute the `put`
36 and `pop` functions for the type of buffer `B`.
37
38
- 39 • The `couple` sentences are also replaced by external C function calls (e.g.,
40 `B_couple(OUT, IN)`).
41
42
- 43 440 • Buffers defined as interfaces of coupled models are removed and their two
44 couple sentences (one outside the model and one inside) are replaced by
45 only one. This operation has to be performed manually, since the tool
46 does not currently support this simplification.
47
48
- 49 • All buffers are replaced by external C objects, with calls to their construc-
50 tor and destructor functions.
51 445
52

53 After the model is flattened, it can be simulated using OpenModelica. An
54 example of simulation run is shown in Fig. 5. Note the alternating oscillatory
55 behavior between the number of sheep and wolves.
56
57
58

Figure 5: Simulation of the hybrid sheep-wolves ABMLib model.

7. Conclusions

450 A new free Modelica library, named ABMLib, has been designed and developed to facilitate the description of agent-based models (ABMs) and their combination with other Modelica models. The design of the library is based in the analyses of the requirements to describe ABMs in Modelica and the current functionality of the language. Agents are described as messages moving through
 455 a flowchart diagram, whose components represent the actions that define the behavior of the agents. This allows to have a variable number of agents in the model during the simulation run. The communication between components of the flowchart diagram is performed using the message passing mechanism proposed by the authors. Additional extensions to this mechanism are also
 460 proposed to describe the interactions among agents. The environment where the agents live is represented using a cellular automaton, and described using the CellularAutomataLib2 library. This allows an efficient simulation of large spatially dependent models, using two-dimensional lattice structures.

465 The main limitation of the library is that it is based in language extensions, and thus it is not supported by current Modelica tools. However, a prototype implementation using the ModelicaCC compiler is presented to demonstrate the

1
2
3
4
5
6
7
8
9 functionality of the library. The message passing mechanism has been imple-
10 mented in ModelicaCC as calls to external functions in C. ABMLib models can
11 be flattened and the resulting code can be simulated using OpenModelica. Some
12 manual manipulations of the model have to be performed during the flattening
13 470 process. The simulation algorithm for ABMs has to be studied and improved.

14
15
16
17 In the future, a full implementation of the message passing mechanism will be
18 developed. The support of ABMLib in other Modelica tools has to be analyzed
19 in order to facilitate the use of the library to different users. The functionality
20 to describe agents will be revised taking into account already used concepts
21 475 such as the BDI (Belief-Desire-Intention) and the process calculus. A better in-
22 tegration between CellularAutomataLib2 and ABMLib has to be performed, to
23 facilitate the description of models with different types of environments. Also,
24 the integration between ABMLib and other agent-based tools will be consid-
25 ered, specially those that support the FIPA standards. Additional flowchart
26 480 components will be included in ABMLib, specially to automatically generate
27 statistical indicators to analyze the simulation results. Also, a better graphical
28 animation will be developed to include more information about the model.

Research highlights for the manuscript **An approach to Agent-Based modeling with Modelica:**

- The requirements to describe ABMs in Modelica are analyzed.
- The new ABMLib library supports the description of ABMs in Modelica.
- Agents are described as messages flowing in a flowchart diagram.
- ABMLib models can be combined with other Modelica models.
- A prototype implementation is presented to demonstrate the modeling functionality.
